<p><u>Erlang Distribution</u></p> <p>n = 5 devices</p> <p>A = 2 erl.</p> <p>a_v = Traffic handled by the v:th device (v = 1, 2, 3, 4, 5)</p> <p>2 erl. → ○ ○ ○ ○ ○ 1 2 3 4 5</p> <p><u>Random hunting:</u></p> $\alpha_v = \frac{A \cdot (1 - E_n(A))}{n} = \frac{2 \cdot (1 - E_5(2))}{5} =$ $= \frac{2 \cdot (1 - 0.0367)}{5} = \underline{\underline{0.385 \text{ erl.}}} \quad (v = 1, 2, 3, 4, 5)$	<p>TXA 10</p> <p>cont.</p>

Sequential hunting

cont:
TXA
10

$$a_v = A \cdot [E_{v-1}(A) - E_v(A)]$$

($v = 1, 2, 3, 4, 5$; $E_0(A) = 1$ if $A > 0$)

Using the Erlang Table, we find

- $E_0(2) = 1$
- $E_1(2) = 0.6667$
- $E_2(2) = 0.4000$
- $E_3(2) = 0.2105$
- $E_4(2) = 0.0952$
- $E_5(2) = 0.0367$

$$a_1 = 2 \cdot [E_0(2) - E_1(2)] = 2 \cdot [1 - 0.6667] = \underline{0.667 \text{ erl.}}$$
$$a_2 = 2 \cdot [E_1(2) - E_2(2)] = 2 \cdot [0.6667 - 0.4000] = \underline{0.533 \text{ erl.}}$$

etc.

Result:

$$a_1 = \underline{0.667 \text{ erl.}} \quad a_2 = \underline{0.533 \text{ erl.}} \quad a_3 = \underline{0.379 \text{ erl.}}$$
$$a_4 = \underline{0.231 \text{ erl.}} \quad a_5 = \underline{0.117 \text{ erl.}}$$

Note that $\frac{1}{5} \cdot \sum_{v=1}^5 a_v = \frac{1}{5} \cdot 1.927 = \underline{0.385 \text{ erl.}}$

We conclude that the mean value of the traffic handled per device is the same for sequential hunting and for random hunting.

<p>Erlang Distribution</p> <div style="text-align: center;"> <p style="margin-left: 100px;">A erl. \longrightarrow ○ ○ ○ ○ ○ 1 2 3 n-1 n</p> <p>(sequential hunting)</p> </div> <p>a_v = Traffic handled by the v:th device</p> <p>$a_v = A \cdot [E_{v-1}(A) - E_v(A)]$</p> <p>($v = 1, 2, \dots, n$; $E_0(A) = 1$ if $A > 0$)</p> <p>Let a = Mean of traffic handled by the different devices =</p> $= \frac{1}{n} \cdot \sum_{v=1}^n a_v$ $a = \frac{1}{n} \cdot \sum_{v=1}^n A \cdot [E_{v-1}(A) - E_v(A)] =$ $= \frac{1}{n} \cdot A \cdot \left[1 + \sum_{v=1}^{n-1} E_v(A) - \sum_{v=1}^{n-1} E_v(A) - E_n(A) \right] =$ $= \frac{A \cdot [1 - E_n(A)]}{n} =$ <p>= Traffic handled per device in a group with random hunting, n devices and traffic offered = A erl.</p>	<p>TXA 11</p>
---	-------------------

Erlang Distribution

TXA
12

$E_{10}(A) = 0.005$ gives $A = \underline{3.961 \text{ erl.}}$

$E_{100}(A) = 0.005$ gives $A = \underline{80.91 \text{ erl.}}$

(according to the Erlang Table)

	n = 10	n = 100
A	3.961 erl.	80.91 erl.
$E_n(A)$	0.005	0.005
$A_1 = 1.1 \cdot A$	4.36 erl.	89.00 erl.
$E_n(A_1)$	0.009	0.024
$A_2 = 1.2 \cdot A$	4.75 erl.	97.09 erl
$E_n(A_2)$	0.014	0.059

If “a” denotes traffic handled per device, we find:

	n = 10	n = 100
A	a = 0.394	a = 0.805
$A_1 = 1.1 \cdot A$	a = 0.432	a = 0.869
$A_2 = 1.2 \cdot A$	a = 0.469	a = 0.914

Denote the length of the interval by T. The distribution function F(x) is by definition:

$$F(x) = P\{T \leq x\}$$

Calculate the complementary distribution function:

$$1 - F(x) = P\{T > x\}$$

$$\underline{0 < j < n:}$$

The interval may end by a call or a termination. Then $T > x$ if

- 1) No call in $(0, x)$ and
- 2) No termination in $(0, x)$.

The probability of 1) is $e^{-\lambda \cdot x}$

The probability of 2) is $e^{-j \cdot \frac{x}{\tau}}$

Consequently,

$$1 - F(x) = e^{-\lambda \cdot x} \cdot e^{-j \cdot \frac{x}{\tau}} = e^{-\frac{A+j}{\tau} \cdot x}$$

$$F(x) = 1 - e^{-\frac{A+j}{\tau} \cdot x}$$

i.e. an exponential distribution with the parameter $\frac{A+j}{\tau}$

The mean of an exponentially distributed random variable is equal to the inverse of the parameter i.e.

$$\underline{\underline{\frac{\tau}{A+j}}}$$

<p>Denote length of conversation by x.</p> $P\{x > 6 \text{ min.}\} = P\{x > 6 \text{ and } A \rightarrow B\} +$ $+ P\{x > 6 \text{ and } B \rightarrow A\} =$ $= P_{A \rightarrow B} \cdot P\{x > 6/A \rightarrow B\} + P_{B \rightarrow A} \cdot P\{x > 6/B \rightarrow A\} =$ $= 0.55 \cdot e^{-\frac{6}{4}} + 0.45 \cdot e^{-\frac{6}{3}} = 0.55 \cdot e^{-1.5} + 0.45 \cdot e^{-2} =$ $= 0.55 \cdot 0.2231 + 0.45 \cdot 0.1353 = \underline{\underline{0.184}}$	<p>TXA 16</p>
<p>Take one of the conversations. The probability that it is still in progress after 1 min. is</p> $e^{-\frac{1}{3}}$ <p>The probability that it has ended before 1 min. is</p> $1 - e^{-\frac{1}{3}}$ <p>The five conversations are independent of each other. So the problem is analog to the situation when we make 5 independent trials in which the probability of success is constant. In this example success = conversation in progress, so by the binomial distribution the required probability is</p> $\binom{5}{2} \cdot \left(e^{-\frac{1}{3}}\right)^2 \cdot \left(1 - e^{-\frac{1}{3}}\right)^{5-2} =$ $= 10 \cdot 0.7165^2 \cdot 0.2835^3 = \underline{\underline{0.117}}$	<p>TXA 17</p>

$$a_9 = \underline{\underline{A(E_8(A) - E_9(A))}}$$

$$P_9 = \frac{A^9}{9!} / \sum_{j=0}^{10} \frac{A^j}{j!} = \frac{10}{A} \cdot \underline{\underline{E_{10}(A)}}$$

$$\underline{\underline{E_9(A)}}$$

P{9 first trunks occupied} =

= P{9 first occupied and 10th free} +

+ P{9 first occupied and 10th occupied}

Left side = $E_9(A)$.

Last term on RHS = P{all 10 occupied} = $E_{10}(A)$.

Consequently:

$$E_9(A) = P(9 \text{ first occ. and } 10\text{th free}) + E_{10}(A)$$

and

$$P\{9 \text{ first occ. and } 10\text{th free}\} = E_9(A) - E_{10}(A)$$

23

The different states are (0), (1), (2) ..., (n), where (p) denotes p busy devices (p = 0,1,...n).

a

The number of different states are thus = n + 1.

We may consider a sequence of n symbols, each of which is either 0 or 1, where 0 denotes a free device and 1 a busy device.

b

Example:

We have 2 possibilities for each device, 0 or 1.

Therefore there are $\underbrace{2 \cdot 2 \cdot 2 \cdot 2 \cdot 2 \cdot 2 \cdot 2 \cdot 2 \cdot 2 \cdot 2 \cdot 2 \cdot 2 \cdot 2 \cdot 2 \cdot 2}_{n \text{ factors}} = 2^n$ different sequences

and so 2^n different states.

The number of different states with exactly p devices engaged is the same as the number of combinations of p out of n elements.

c

Thus, the number of different states with exactly p devices engaged is

$$\underline{\underline{\binom{n}{p} \quad (p = 0, 1, \dots, n)}}$$

Note:

$$\sum_{p=0}^n \binom{n}{p} = (1+1)^n = 2^n \text{ (compare with b)}$$

d

In all p devices engaged, where $p \geq x$. Among the $(n-x)$ devices, there are thus $(p-x)$ devices engaged. Analogously to c) we can then state:

The number of different states with x specified devices engaged and, simultaneously, exactly p devices engaged is

$$\frac{\binom{n-x}{p-x}}{\binom{n}{p}} \quad (p = x, x+1, \dots, n; \quad x = 0, 1, \dots, n)$$

$$[p] = P\{\text{exactly any } p \text{ devices being engaged}\}.$$

$$(p = 0, 1, \dots, n).$$

e

A specified state with exactly p devices engaged has the probability

$$\frac{[p]}{\binom{n}{p}}$$

if we have random hunting, as there are in all $\binom{n}{p}$ different states with exactly p devices engaged according to c) and as all those different states will have one and the same probability.

cont.

In order to find

$$h(x, p) = P\{x \text{ specified devices engaged, and,} \\ \text{simultaneously, exactly } p \text{ devices engaged}\}$$

we shall thus add a certain number of equal probabilities,

namely $\frac{[p]}{\binom{n}{p}}$; that number is, according to d), $\binom{n-x}{p-x}$.

Therefore,

$$h(x, p) = \binom{n-x}{p-x} \cdot \frac{[p]}{\binom{n}{p}} \quad (p = x, x+1, \dots, n)$$

Now, we have that

$$H(x) = P\{x \text{ specified devices engaged}\}$$

must be equal to

$$H(x) = \sum_{p=x}^n h(x, p)$$

so the result is:

$$H(x) = \sum_{p=x}^n \binom{n-x}{p-x} \cdot \frac{[p]}{\binom{n}{p}}$$
