

Recommendation ITU-R P.2170-0

(09/2025)

P Series: Radio-wave propagation

Methods and models for predicting lunar radio-wave propagation characteristics

Foreword

The role of the Radiocommunication Sector is to ensure the rational, equitable, efficient and economical use of the radio-frequency spectrum by all radiocommunication services, including satellite services, and carry out studies without limit of frequency range on the basis of which Recommendations are adopted.

The regulatory and policy functions of the Radiocommunication Sector are performed by World and Regional Radiocommunication Conferences and Radiocommunication Assemblies supported by Study Groups.

Policy on Intellectual Property Right (IPR)

ITU-R policy on IPR is described in the Common Patent Policy for ITU-T/ITU-R/ISO/IEC referenced in Resolution ITU-R 1. Forms to be used for the submission of patent statements and licensing declarations by patent holders are available from <https://www.itu.int/ITU-R/go/patents/en> where the Guidelines for Implementation of the Common Patent Policy for ITU-T/ITU-R/ISO/IEC and the ITU-R patent information database can also be found.

Series of ITU-R Recommendations

(Also available online at <https://www.itu.int/publ/R-REC/en>)

Series	Title
BO	Satellite delivery
BR	Recording for production, archival and play-out; film for television
BS	Broadcasting service (sound)
BT	Broadcasting service (television)
F	Fixed service
M	Mobile, radiodetermination, amateur and related satellite services
P	Radio-wave propagation
RA	Radio astronomy
RS	Remote sensing systems
S	Fixed-satellite service
SA	Space applications and meteorology
SF	Frequency sharing and coordination between fixed-satellite and fixed service systems
SM	Spectrum management
SNG	Satellite news gathering
TF	Time signals and frequency standards emissions
V	Vocabulary and related subjects

Note: This ITU-R Recommendation was approved in English under the procedure detailed in Resolution ITU-R 1.

RECOMMENDATION ITU-R P.2170-0

Methods and models for predicting lunar radio-wave propagation characteristics

Question ITU-R 237/3

(2025)

Scope

This Recommendation provides methods that predict the attenuation relative to free-space¹ and other radio-wave propagation characteristics described in Parts C and D of the Annex, needed for planning networks and systems operating on or near the lunar surface in the frequency range from 1 MHz to 37 GHz².

Keywords

Exosphere, regolith, bedrock, irregular lunar model (ILM)

Acronyms/Abbreviations/Glossary

LoS line-of-sight

Related ITU-R Recommendations

Recommendation ITU-R P.341 – The concept of transmission loss for radio links

Recommendation ITU-R P.525 – Calculation of free-space attenuation

Recommendation ITU-R P.618 – Propagation data and prediction methods required for the design of Earth-space telecommunication systems

NOTE – The latest edition of the Recommendation in force should be used.

The ITU Radiocommunication Assembly,

considering

- a) that the lunar environment interacting with radio waves includes the lunar exosphere, regolith, and bedrock;
- b) that, at frequencies above the exosphere plasma frequency, a maximum of approximately 220 kHz at the lunar surface, the lunar exosphere can be treated as free space;
- c) that the characteristics of the complex relative permittivity of the lunar regolith and lunar bedrock is needed in characterizing several radio-wave propagation mechanisms in the lunar environment;
- d) that radio-wave propagation in the lunar environment is needed in characterizing several radio-wave propagation mechanisms, including diffraction, reflection and scattering;

¹ Basic transmission loss defined in § 1.2 of Recommendation ITU-R P.341 is the sum of: a) attenuation relative to free-space in this Recommendation, and b) free-space basic transmission loss defined in Recommendation ITU-R P.525.

² See §§ C.1.5 and C.1.6.

e) that radio-wave propagation in the lunar environment can be characterized by the attenuation statistics relative to free-space;

f) that the propagation characteristics of lunar point-to-area and point-to-point systems are necessary elements for radio-wave propagation prediction in the lunar environment,

recommends

that the Annex to this Recommendation should be considered to predict statistics of the attenuation relative to free-space for point-to-area and point-to-point systems operating on or near the lunar surface in the frequency range from 1 MHz to 37 GHz³.

Introduction

This Annex is divided into the following four Parts:

- Part A: The Irregular Lunar Model (ILM): Point-to-area mode
- Part B: The Irregular Lunar Model (ILM): Point-to-point mode
- Part C: Electrical characteristics of the surface of the Moon
- Part D: Prediction of free-space propagation loss

The ILM predicts the median and statistical attenuation for point-to-area and point-to-point links on or near the lunar surface. The ‘point-to-area mode’ prediction method predicts the path attenuation between a transmitter and receiver over a specific area using statistical or general terrain characteristics. The ‘point-to-point mode’ prediction method predicts the path attenuation between specific transmitter and receiver locations using specific detailed terrain data and characteristics. In both cases, the transmit and receive antennas are assumed to be lossless linearly polarized (horizontal or vertical) isotropic antennas, and the receive antenna is assumed to be matched to the polarization of the incident signal. Depending on the antenna beamwidth and distance, the attenuation for systems with narrowbeam antennas may not be within the scope of this Recommendation. The attenuation for systems with circularly polarized antennas is not within the scope of this Recommendation.

Equation (A-18) calculates the median path attenuation for the point-to-area mode as a function of distance, and equation (B-16) calculates the median path attenuation for the point-to-point mode as a function of distance.

The attenuation relative to free-space that is not exceeded for the fraction of the area of interest for the point-to-area mode is calculated in § A.1.7, and the attenuation relative to free-space that is not exceeded for the fraction of equivalent terrain profiles for the point-to-point mode is calculated in § B.1.7. The function $A_{ref}(p)$ in the main function that predicts the attenuation relative to free-space. Other functions, such as $A_{diff}(s)$, with an argument of s are referenced by $A_{ref}(p)$ with the appropriate argument.

The propagation loss between: a) systems on or near the lunar surface and systems in lunar orbit, and b) systems on or near the lunar surface and systems orbiting the Earth, where the line-of-sight path is unobstructed and there are no surface reflections is specified in § B.1.

PART A

The Irregular Lunar Model (ILM): Point-to-area mode**A.1 Introduction**

The Irregular Lunar Model (ILM) point-to-area mode is a general-purpose radio propagation prediction method that predicts $A_{ref}(p)$, the attenuation relative to free-space that is not exceeded for the fraction of the area of interest, p ($0 < p < 1$), for lunar radio systems in the frequency in range from 20 MHz to 37 GHz.

The input parameters for the ILM point-to-area mode are shown in Table 1.

TABLE 1

Irregular lunar model input parameters for the point-to-area mode

f	Frequency (MHz)
d	Horizontal smooth surface distance between the terminals (m); $500 \text{ km} > d > 0.5 \text{ km}$
p	Fraction of locations ($0 < p < 1$)
h_{g1}, h_{g2}	Terminals' antenna structural (i.e. electrical centre) heights above a sphere of radius 1 737 400 m; $0.5 \text{ m} < h_{gx} < 3 \text{ km}$, where the elevation angle from the antenna to the horizon $< 200 \text{ mrad}$.
Δh	Terrain irregularity (m)
Z_g	Surface transfer impedance of the lunar surface (regolith)
ψ_i	Elevation angle from terminal to terminal
T_{pol}	Transmit polarization (e.g. horizontal or vertical)

Calculate the wavenumber, k , from the frequency, f , as follows:

$$k = \frac{2\pi}{\lambda} = \frac{2\pi f}{c} (\text{m}^{-1}) \quad (\text{A-1})$$

where the speed of light in vacuum, $c = 299\,792\,458 \text{ m/s}$. Since the units of frequency, f , are MHz, the wavenumber, k , is:

$$k = \frac{f}{f_0} (\text{m}^{-1}) \quad (\text{A-2})$$

where $f_0 = 47.713\,451\,59 \text{ MHz-m}$.

The physical radius of the Moon, a_e , is 1 737 400 m, and the effective curvature of the Moon, γ_e , is $\frac{1}{a_e} \text{ m}^{-1}$.

The surface transfer impedance of the lunar surface (regolith), Z_g , is a complex, dimensionless constant which depends on the relative permittivity of the lunar surface, $\epsilon_r = \epsilon' + i \epsilon''$. The relative permittivity should be calculated as a representative value considering the path profile. In the absence of a representative value, the value at the mid-point of the path should be used. If the local mineral content of TiO_2 and FeO are known, the prediction method in Part C can be used. In the absence of local data, the real part of the surface relative permittivity, ϵ' , can be assumed to be 2.0. The real part of the relative permittivity of the lunar atmosphere, ϵ' , can be assumed to be 1.0 for frequencies within the range of this model.

The polarization of the radio signal's electric field vector, T_{pol} (i.e. horizontal, which is defined as perpendicular to the plane of incidence at the ground reflection point, or vertical, which is defined as parallel to the plane of incidence at the ground reflection point).

At the elevation angle ψ_i , polarization p , the regolith surface transfer impedance can be written as:

$$Z_g = \left\{ \frac{1 - \mathcal{R}_0^p(\psi_i)}{1 + \mathcal{R}_0^p(\psi_i)} \right\} \sin \psi_i, \quad T_{pol} = v, h \quad (\text{A-3})$$

For a homogeneous regolith, the reflection coefficients $\mathcal{R}_0^{Tpol}(\psi_i)$ in equation (A-3) can be replaced by the corresponding Fresnel reflection coefficients of:

$$\mathcal{R}_0^{Tpol}(\psi_i) = \begin{cases} \frac{\epsilon_r \sin \psi_i - \sqrt{\epsilon_r - \cos^2 \psi_i}}{\epsilon_r \sin \psi_i + \sqrt{\epsilon_r - \cos^2 \psi_i}}, & T_{pol} = v \\ \frac{\sin \psi_i - \sqrt{\epsilon_r - \cos^2 \psi_i}}{\sin \psi_i + \sqrt{\epsilon_r - \cos^2 \psi_i}}, & T_{pol} = h \end{cases} \quad (\text{A-4})$$

Leading to:

$$Z_g = \begin{cases} \frac{\sqrt{\epsilon_r - \cos^2 \psi_i}}{\epsilon_r}, & T_{pol} = v \\ \sqrt{\epsilon_r - \cos^2 \psi_i}, & T_{pol} = h \end{cases} \quad (\text{A-5})$$

At near grazing incidence, $\psi_i \sim 0_i$, Z_g can be approximated as follows:

$$Z_g = \begin{cases} \frac{\sqrt{\epsilon_r - 1}}{\epsilon_r}, & T_{pol} = v \\ \sqrt{\epsilon_r - 1}, & T_{pol} = h \end{cases} \quad (\text{A-6})$$

There are two cases for terminal siting: 1) mobile terminals, and 2) fixed terminals.

If the local lunar terrain topography is known, the terrain irregularity parameter, Δh , for a set of representative paths between the transmit antenna and representative receive antennas can be determined as follows.

For each representative path:

- 1) for a line-of-sight path, determine $d_{tx,horizon}$ (m), the distance from the transmit antenna electric centre to the horizon defined by the line-of-sight from the transmit antenna electrical centre to the receive antenna electrical centre; and for a non-line-of-sight path, determine $d_{tx,horizon}$ (m), the distance from the transmit antenna electric centre to the horizon defined by the intersection of a) line-of-sight from the transmit antenna electrical centre to the receive antenna electrical centre and b) the intervening obstacle;
- 2) for a line-of-sight path, determine $d_{rx,horizon}$ (m), the distance from the receive antenna electric centre to the horizon defined by the line-of-sight from the receive antenna electrical centre to the transmit antenna electrical centre; and for a non-line-of-sight path, determine $d_{rx,horizon}$ (m), the distance from the receive antenna electric centre to the horizon defined by the intersection of a) line-of-sight from the receive antenna electrical centre to the transmit antenna electrical centre and b) the intervening obstacle;
- 3) determine the elevation of the lunar surface relative to a sphere of radius 1 737 400 m at a set of equidistant points on the lunar surface along the path from transmit antenna to the receive antenna excluding the region of radius $\min(15 h_{g_1}, 0.1 d_{tx,horizon})$ m around the transmit antenna and the region of radius $\min(15 h_{g_2}, 0.1 d_{rx,horizon})$ m around the receive antenna;
- 4) calculate $d_x = d - \min(15 h_{g_1}, 0.1 d_{tx,horizon}) - \min(15 h_{g_2}, 0.1 d_{rx,horizon})$;
- 5) perform a linear least-squares fit to the set of equidistant points along the path of length d_x ;

- 6) calculate the residual differences between the set of equidistant points along the path of length d_x and the linear least squares fit;
- 7) sort the set of residual differences in ascending or descending order;
- 8) delete the top 10% and the bottom 10% of the sorted set of differences;
- 9) $\Delta h(d_x)$ is equal to the difference between the maximum and minimum values of the sorted residual differences;
- 10) then, Δh for each representative path is: $\Delta h = \frac{\Delta h(d_x)}{\left(1 - 0.8 e^{-\frac{d_x}{5 \times 10^4}}\right)} \text{ (m)}.$

The net Δh is the average Δh for the set of representative paths.

In the absence of local lunar topographic data, a suggested value from Table 2 can be assumed.

TABLE 2

Suggested values for the lunar terrain irregularity parameter, Δh (m)

Lunar surface	Δh (m)
Smooth	0-1 500
Average crater field	1 500-3 500
Major crater field	3 500-5 000
Extremely rugged crater field	> 5 000
For an average lunar surface, use $\Delta h = 3\ 000$ m.	

A.1.1 Preparatory calculations

Define the transmit terminal as $j = 1$ and the receive terminal as $j = 2$. If a terminal is a mobile terminal, then:

$$h_{ej} = h_{gj} \text{ (m)} \quad \text{for } j = 1, 2 \quad (\text{A-7})$$

and, if the terminal is a fixed terminal:

$$B_j = 10 \text{ (m)} \quad \text{for } j = 1, 2 \quad (\text{A-8})$$

in which case,

$$B'_j = (B_j - 1) \sin\left(\frac{\pi}{2} \min\left(\frac{h_{gj}}{5}, 1\right)\right) + 1 \quad (\text{A-9})$$

$B'_j = B_j$ if $h_{gj} \geq 5$ m. The effective height of the j^{th} terminal, h_{ej} ($j = 1$ or 2), is then:

$$h_{ej} = h_{gj} + B'_j e^{-\frac{2h_{gj}}{\Delta h}} \quad \text{for } j = 1, 2 \quad (\text{A-10})$$

Calculate the smooth lunar horizon distances, d_{lsj} :

$$d_{lsj} = \sqrt{2h_{ej}a_e} \quad \text{for } j = 1, 2 \text{ (m)} \quad (\text{A-11})$$

Then, the terminals' radio horizon distances, d_{lj} , and elevation angles, θ_{ej} ⁴, are:

⁴ The units of angles, θ , in this Part are radians.

$$d_{lj} = d_{lsj} e^{-0.07 \sqrt{\frac{\Delta h}{\max(h_{ej}, 5)}}} \quad \text{for } j = 1, 2 \text{ (m)} \quad (\text{A-12})$$

and

$$\theta_{ej} = -\frac{[2h_{ej} + 0.65\Delta h(d_{lsj}/d_{lj} - 1)]}{d_{lsj}} \quad \text{for } j = 1, 2 \quad (\text{A-13})$$

The combined smooth lunar radio horizon distance, d_{ls} , the combined irregular terrain radio horizon distance, d_l , and the combined irregular terrain radio horizon elevation angles, θ_e , are then:

$$d_{ls} = d_{ls1} + d_{ls2} \quad (\text{A-14})$$

$$d_l = d_{l1} + d_{l2} \quad (\text{A-15})$$

$$\theta_e = \max(\theta_{e1} + \theta_{e2}, -d_l \gamma_e) \quad (\text{A-16})$$

and $\Delta h(s)$, which is a function of distance, s , is:

$$\Delta h(s) = \Delta h \left(1 - 0.8 e^{-\frac{s}{5 \times 10^4}} \right) \quad (\text{m}) \quad (\text{A-17})$$

A.1.2 Reference attenuation

The reference attenuation, A_{ref} , is the predicted median attenuation relative to free-space that would be observed on similar paths. A_{ref} is the following piecewise function of path horizontal distance, d :

$$A_{ref}(d) = \begin{cases} \max \left[0, A_{el} + K_1 d + K_2 \ln \left(\frac{d}{d_{ls}} \right) \right] & \text{for } d \leq d_{ls} \\ A_{ed} + m_d d & \text{for } d > d_{ls} \end{cases} \quad (\text{dB}) \quad (\text{A-18})$$

where A_{el} is defined in equation (A-76), A_{ed} is defined in equation (A-25), and the coefficients K_1 , K_2 , and m_d are calculated in the following sections. The range $d \leq d_{ls}$ is defined as the line-of-sight range, and the range $d \geq d_{ls}$ is defined as the diffraction range. Note that A_{ref} is continuous at $d = d_{ls}$.

A.1.3 Coefficients for the diffraction range

The coefficients for the diffraction range are calculated by evaluating the diffraction attenuation, $A_{diff}(d)$, at two distances, d_3 and d_4 , which are beyond line-of-sight. Calculate:

$$d_3 = \max(d_{ls}, d_l + 1.3787X_{ae}) \quad (\text{A-19})$$

$$d_4 = d_3 + 2.7574X_{ae} \quad (\text{A-20})$$

$$A_3 = A_{diff}(d_3) \quad (\text{A-21})$$

$$A_4 = A_{diff}(d_4) \quad (\text{A-22})$$

where:

$$X_{ae} = (k\gamma_e^2)^{-\frac{1}{3}} = a_e \left(\frac{2\pi a_e}{\lambda} \right)^{-\frac{1}{3}} \quad (\text{A-23})$$

and the function A_{diff} is defined in equation (A-26).

The parameters m_d and A_{ed} are:

$$m_d = \frac{A_4 - A_3}{d_4 - d_3} \quad \left(\frac{\text{dB}}{\text{m}} \right) \quad (\text{A-24})$$

$$A_{ed} = A_3 - m_d d_3 = \frac{A_3 d_4 - A_4 d_3}{d_4 - d_3} \quad (\text{dB}) \quad (\text{A-25})$$

A.1.4 Diffraction attenuation function

The diffraction attenuation function, $A_{diff}(s)$, is a weighted combination of the ‘double knife-edge’ attenuation, $A_k(s)$, and “rounded lunar” diffraction attenuation, $A_r(s)$:

$$A_{diff}(s) = (1 - w(s))A_k(s) + w(s)A_r(s) \quad (\text{dB}) \quad (\text{A-26})$$

$A_k(s)$ is defined in equation (A-29), $A_r(s)$ is defined in equation (A-41), and the weighting factor, $w(s)$, is defined as:

$$w(s) = \frac{1}{1 + 0.1\sqrt{Q(s)}} \quad (\text{A-27})$$

where:

$$Q(s) = \min\left(\frac{\Delta h(s)}{\lambda}, 1\,000\right) \left[\sqrt{\frac{h_{e1}h_{e2}+C}{h_{g1}h_{g2}+C}} + \frac{d_l + a_e\theta_e}{s} \right] \quad (\text{A-28})$$

and $C = 0$.

The median ‘double knife-edge’ diffraction attenuation for the two irregular lunar radio horizons, $A_k(s)$, is:

$$A_k(s) = Fn(v_1(s)) + Fn(v_2(s)) \quad (\text{dB}) \quad (\text{A-29})$$

where:

$$Fn(z) = -20 \log_{10} \left(\left| \frac{1}{\sqrt{2i}} \int_z^\infty e^{i\frac{\pi}{2}u^2} du \right| \right) \quad (\text{A-30})$$

$$= -20 \log_{10} \left(\left| \left[\frac{1+i}{2\sqrt{2i}} \operatorname{erfc} \left(\frac{\sqrt{\pi}}{2} (1-i)z \right) \right] \right| \right) \quad (\text{A-31})$$

$$= -20 \log_{10} \left(\left| \left[\frac{1+i}{\sqrt{2i}} Q \left(\sqrt{\frac{\pi}{2}} (1-i)z \right) \right] \right| \right) \quad (\text{A-32})$$

$$v_j(s) = \frac{\theta(s)}{2} \sqrt{\frac{2d_{lj}(s-d_l)}{\lambda(s-d_l+d_{lj})}} \quad \text{for } j = 1, 2 \quad (\text{A-33})$$

and:

$$\theta(s) = \theta_e + s\gamma_e \quad (\text{A-34})$$

The ‘rounded-lunar’ diffraction attenuation is based on a ‘three radii’ method applied to the solution of the smooth spherical diffraction problem. Calculate γ_0 , γ_1 and γ_2 as follows:

$$\gamma_0 = \frac{\theta(s)}{s-d_l} \quad (\text{A-35})$$

$$\gamma_j = \frac{2h_{ej}}{d_{lj}^2} \quad \text{for } j = 1, 2 \quad (\text{A-36})$$

Set:

$$\alpha_j = \left(\frac{k}{\gamma_j} \right)^{\frac{1}{3}} \quad \text{for } j = 0, 1, 2 \quad (\text{A-37})$$

and:

$$K_j = \frac{1}{i\alpha_j Z_g} \quad \text{for } j = 0, 1, 2 \quad (\text{A-38})$$

Define the dimensionless distances:

$$x_0 = AB(K_0) \alpha_0 \theta(s) + x_1 + x_2 \quad (\text{A-39})$$

and:

$$x_j = AB(K_j) \alpha_j \gamma_j d_{lj} \quad \text{for } j = 1, 2 \quad (\text{A-40})$$

where $A = 63.798$. Note that only x_0 depends on s . The ‘rounded-lunar’ diffraction attenuation, $A_r(s)$, is:

$$A_r(s) = G(x_0) - F(x_1, K_1) - F(x_2, K_2) - C_1(K_0) \quad (\text{A-41})$$

where the functions $G(x)$, $F(x, K)$, $C_1(K)$ and $B(K)$ are defined in § A.2.

A.1.5 Coefficients for the line-of-sight range

Set:

$$d_2 = d_{ls} \quad (\text{A-42})$$

and:

$$A_2 = A_{ed} + m_d d_2 \quad (\text{dB}) \quad (\text{A-43})$$

There are two general cases, depending upon the sign of A_{ed} .

Case 1: If $A_{ed} \geq 0$, set:

$$d_0 = \min\left(\frac{d_l}{2}, 1.908 k h_{e1} h_{e2}\right) \quad (\text{A-44})$$

$$d_1 = \frac{3}{4} d_0 + \frac{d_l}{4} \quad (\text{A-45})$$

$$A_0 = A_{los}(d_0) \quad (\text{dB}) \quad (\text{A-46})$$

$$A_1 = A_{los}(d_1) \quad (\text{dB}) \quad (\text{A-47})$$

Calculate:

$$K'_2 = \max\left(0, \frac{(A_1 - A_0)(d_2 - d_0) - (A_2 - A_0)(d_1 - d_0)}{(d_2 - d_0) \ln\left(\frac{d_1}{d_0}\right) - (d_1 - d_0) \ln\left(\frac{d_2}{d_0}\right)}\right) \quad (\text{A-48})$$

and:

$$K'_1 = \frac{A_2 - A_0 - K'_2 \ln\left(\frac{d_2}{d_0}\right)}{d_2 - d_0} \quad (\text{A-49})$$

If $K'_1 \geq 0$, set:

$$K_1 = K'_1 \quad (\text{A-50})$$

$$K_2 = K'_2 \quad (\text{A-51})$$

however, if $K'_1 < 0$, set:

$$K''_2 = \frac{A_2 - A_0}{\ln\left(\frac{d_2}{d_0}\right)} \quad (\text{A-52})$$

If $K''_2 \geq 0$, set:

$$K_1 = 0 \quad (\text{A-53})$$

$$K_2 = K''_2 \quad (\text{A-54})$$

However, if $K_2'' < 0$, set:

$$K_1 = m_d \quad (\text{A-55})$$

$$K_2 = 0 \quad (\text{A-56})$$

Case 2: If $A_{ed} < 0$, set:

$$d_0 = 1.908kh_{e1}h_{e2} \quad (\text{A-57})$$

$$d_1 = \max\left(-\frac{A_{ed}}{m_d}, \frac{d_l}{4}\right) \quad (\text{A-58})$$

If $d_0 < d_1$, set:

$$A_0 = A_{los}(d_0) \quad (\text{dB}) \quad (\text{A-59})$$

$$A_1 = A_{los}(d_1) \quad (\text{dB}) \quad (\text{A-60})$$

and:

$$K_2' = \max\left(0, \frac{(A_1 - A_0)(d_2 - d_0) - (A_2 - A_0)(d_1 - d_0)}{(d_2 - d_0)\ln\left(\frac{d_1}{d_0}\right) - (d_1 - d_0)\ln\left(\frac{d_2}{d_0}\right)}\right) \quad (\text{A-61})$$

If $K_2' \neq 0$, calculate:

$$K_1' = \frac{A_2 - A_0 - K_2' \ln\left(\frac{d_2}{d_0}\right)}{d_2 - d_0} \quad (\text{A-62})$$

If $K_1' \geq 0$, set:

$$K_1 = K_1' \quad (\text{A-63})$$

$$K_2 = K_2' \quad (\text{A-64})$$

If $K_1' < 0$, set:

$$K_2'' = \frac{A_2 - A_0}{\ln\left(\frac{d_2}{d_0}\right)} \quad (\text{A-65})$$

If $K_2'' \geq 0$, then:

$$K_1 = 0 \quad (\text{A-66})$$

$$K_2 = K_2'' \quad (\text{A-67})$$

If $K_2'' < 0$, then:

$$K_1 = m_d \quad (\text{A-68})$$

$$K_2 = 0 \quad (\text{A-69})$$

If $d_0 \geq d_1$ or $K_2' = 0$, then:

$$A_1 = A_{los}(d_1) \quad (\text{dB}) \quad (\text{A-70})$$

$$K_1'' = \frac{A_2 - A_1}{d_2 - d_1} \quad (\text{A-71})$$

If $K_1'' > 0$, then:

$$K_1 = K_1'' \quad (\text{A-72})$$

$$K_2 = 0 \quad (\text{A-73})$$

Otherwise, set:

$$K_1 = m_d \quad (\text{A-74})$$

$$K_2 = 0 \quad (\text{A-75})$$

Finally, set:

$$A_{el} = A_2 - K_1 d_2 \quad (\text{dB}) \quad (\text{A-76})$$

A.1.6 The line-of-sight range attenuation function

The line-of-sight range attenuation function, $A_{los}(s)$, is the weighted combination of the ‘extrapolated/extended diffraction range’ attenuation, $A_d(s)$, and the ‘two-ray’ attenuation, $A_t(s)$:

$$A_{los}(s) = (1 - w)A_d(s) + wA_t(s) \quad (\text{dB}) \quad (\text{A-77})$$

$A_d(s)$ is defined in equation (A-79), $A_t(s)$ is defined in equation (A-86), and the weighting function, w , is:

$$w = \frac{1}{1 + \frac{D_1 k \Delta h}{\max(D_2, d_{ls})}} \quad (\text{A-78})$$

where $D_1 = 47.7$ m, and $D_2 = 10$ km. The ‘extended diffraction range’ attenuation is:

$$A_d(s) = A_{ed} + m_d s \quad (\text{dB}) \quad (\text{A-79})$$

For the “two-ray” attenuation, set:

$$\sin \psi(s) = \frac{h_{e1} + h_{e2}}{\sqrt{s^2 + (h_{e1} + h_{e2})^2}} \quad (\text{A-80})$$

and:

$$R'_e(s) = \frac{\sin \psi(s) - Z_g}{\sin \psi(s) + Z_g} e^{-k \sigma_h(s) \sin \psi(s)} \quad (\text{A-81})$$

where:

$$\sigma_h(s) = \frac{\Delta h(s)}{1.282} e^{-\frac{\sqrt[4]{\Delta h(s)}}{2}} \quad (\text{A-82})$$

Set:

$$\delta'(s) = 2 \frac{k h_{e1} h_{e2}}{s} \quad (\text{A-83})$$

The effective reflection coefficient, $R_e(s)$, is:

$$R_e(s) = \begin{cases} R'_e(s) & \text{for } |R'_e(s)| \geq \max(0.5, \sqrt{\sin \psi(s)}) \\ \frac{R'_e(s)}{|R'_e(s)|} \sqrt{\sin \psi(s)} & \text{otherwise} \end{cases} \quad (\text{A-84})$$

The phase difference, $\delta(s)$, is:

$$\delta(s) = \begin{cases} \delta'(s) & \text{for } \delta'(s) \leq \frac{\pi}{2} \\ \pi - \frac{(\frac{\pi}{2})^2}{\delta'(s)} & \text{otherwise} \end{cases} \quad (\text{A-85})$$

The ‘two-ray’ attenuation, $A_t(s)$, is then:

$$A_t(s) = -20 \log_{10} |1 + R_e(s) e^{i\delta(s)}| \quad (\text{dB}) \quad (\text{A-86})$$

A.1.7 Location variability

$A_{ref}(p)$, the attenuation relative to free-space that is not exceeded for the fraction of the area of interest, p ($0 < p < 1$) is calculated as follows:

Calculate $\Delta h(d)$, σ , and z as follows, where d is the entire path length:

$$\Delta h(d) = \Delta h \left(1 - 0.8 e^{-\frac{d_x}{5 \times 10^4}} \right) \quad (\text{A-87})$$

$$\sigma = \frac{10 k \Delta h(d)}{k \Delta h(d) + 13} \quad (\text{A-88})$$

$$z = Q^{-1}(p) \quad (\text{A-89})$$

where d is the entire path length.

Then:

$$A_{ref}(p) = A_{ref} + \sigma z \quad (\text{dB}) \quad (\text{A-90})$$

A.2 Functions $G(x)$, $F(x, K)$, $C_1(K)$ and $B(K)$

$$F(x, K) = \begin{cases} F_2(x, K) & \text{for } 0 < x \leq 200 \\ G(x) + 0.013 x e^{-\frac{x}{200}} [F_1(x) - G(x)] & \text{for } 200 < x < 2\,000 \\ G(x) & \text{for } x \geq 2\,000 \end{cases} \quad (\text{A-91})$$

where:

$$G(x) = 0.05751 x - 10 \log_{10} x \quad (\text{A-92})$$

$$F_1(x) = 40 \log_{10}(\max(x, 1)) - 117 \quad (\text{A-93})$$

$$F_2(x, K) = \begin{cases} F_1(x) & \text{for } |K| < 10^{-5} \text{ or } x (-\log_{10}|K|)^3 > 450 \\ 2.5 x \frac{10^{-5} x^2}{|K|} + 20 \log_{10}(|K|) - 15 & \text{otherwise} \end{cases} \quad (\text{A-94})$$

$$C_1(K) = 20 \quad (\text{A-95})$$

$$B(K) = 1.607 - |K| \quad (\text{A-96})$$

PART B

The irregular lunar model (ILM): Point-to-point mode**B.1 Introduction**

The Irregular Lunar Model (ILM) point-to-point mode is a general-purpose radio-wave propagation prediction method that predicts $A_{ref}(p)$, the attenuation relative to free-space that is not exceeded for the fraction of equivalent terrain profiles, p ($0 < p < 1$), for lunar radio systems in the frequency in range from 20 MHz to 37 GHz.

The input parameters for the ILM point-to-point mode are shown in Table 3.

TABLE 3

Irregular lunar model input parameters for the point-to-point mode

f	Frequency (MHz).
h_i	Vector of uniformly-spaced horizontal distances between terminals (m); $h_i < 100$ m. Min/max smooth surface distance between terminals $500 \text{ km} > d > 0.1 \text{ km}$
p	Fraction of locations ($0 < p < 1$)
h_{g1}, h_{g2}	Terminals' antenna structural (i.e. electrical centre) heights above a sphere of radius 1 737 400 m; $0.5 \text{ m} < h_{gx} < 3 \text{ km}$, where the elevation angle from the antenna to the horizon $< 200 \text{ mrad}$
h_i	Lunar terrain elevations at uniformly-space horizontal distances between terminals (m)
d	Great circle distance between the transmit and receive terminals
Z_g	Surface transfer impedance of the lunar surface (regolith)
ψ_i	Elevation angle from terminal to terminal
T_{pol}	Transmit polarization (e.g. horizontal or vertical)

Calculate the wavenumber, k , from the frequency, f , as follows:

$$k = \frac{2\pi}{\lambda} = \frac{2\pi f}{c} \quad (\text{m}^{-1}) \quad (\text{B-1})$$

where the speed of light in a vacuum, $c = 299\,792\,458 \text{ m/s}$. Since the units of frequency, f , are MHz, the wavenumber, k , is:

$$k = \frac{f}{f_0} \quad (\text{m}^{-1}) \quad (\text{B-2})$$

where $f_0 = 47.713\,451\,59 \text{ MHz-m}$.

The physical radius of the Moon, a_e , is 1 737 400 m, and the effective curvature of the Moon, γ_e , is $\frac{1}{a_e} \text{ m}^{-1}$.

The surface transfer impedance of the lunar surface (regolith), Z_g , is a complex, dimensionless constant which depends on the relative permittivity of the lunar surface, $\epsilon_r = \epsilon' + i\epsilon''$. The relative permittivity should be calculated as a representative value considering the path profile. In the absence of a representative value, the value at the mid-point of the path should be used. If the local mineral content of TiO_2 and FeO are known, the prediction method in Part B can be used. In the absence of local data, the real part of the surface relative permittivity, ϵ' , can be assumed to be 2.0. The real part

of the relative permittivity of the lunar atmosphere, ε' , can be assumed to be 1.0 for frequencies within the range of this model.

The polarization of the radio signal's electric field vector, T_{pol} , (i.e. horizontal, which is defined as perpendicular to the plane of incidence at the ground reflection point, or vertical, which is defined as parallel to the plane of incidence at the ground reflection point). The surface transfer impedance of the lunar surface, Z_g , is:

At the elevation angle ψ_i , polarization p , regolith surface transfer impedance can be written as:

$$Z_g = \left\{ \frac{1 - \mathcal{R}_0^p(\psi_i)}{1 + \mathcal{R}_0^p(\psi_i)} \right\} \sin \psi_i, \quad T_{pol} = v, h \quad (B-3)$$

For a homogeneous regolith, the reflection coefficients $\mathcal{R}_0^{Tpol}(\psi_i)$'s in equation (A-3) can be replaced by the corresponding Fresnel reflection coefficients of:

$$\mathcal{R}_0^{Tpol}(\psi_i) = \begin{cases} \frac{\varepsilon_r \sin \psi_i - \sqrt{\varepsilon_r - \cos^2 \psi_i}}{\varepsilon_r \sin \psi_i + \sqrt{\varepsilon_r - \cos^2 \psi_i}}, & T_{pol} = v \\ \frac{\sin \psi_i - \sqrt{\varepsilon_r - \cos^2 \psi_i}}{\sin \psi_i + \sqrt{\varepsilon_r - \cos^2 \psi_i}}, & T_{pol} = h \end{cases} \quad (B-4)$$

Leading to:

$$Z_g = \begin{cases} \frac{\sqrt{\varepsilon_r - \cos^2 \psi_i}}{\varepsilon_r}, & T_{pol} = v \\ \sqrt{\varepsilon_r - \cos^2 \psi_i}, & T_{pol} = h \end{cases} \quad (B-5)$$

At near grazing incidence $\psi_i \sim 0$, Z_g can be approximated as follows:

$$Z_g = \begin{cases} \frac{\sqrt{\varepsilon_r - 1}}{\varepsilon_r}, & T_{pol} = v \\ \sqrt{\varepsilon_r - 1}, & T_{pol} = h \end{cases} \quad (B-6)$$

There are two cases for terminal siting: 1) mobile terminals, and 2) fixed terminals.

The terrain irregularity parameter, Δh , for the path between the transmit and receive antennas can be determined as follows.

FIGURE 1
Example horizon distances and angles

P.2170-01

For each representative path:

- 1) Referring to Fig. 1, determine d_{l1} (m) and θ_{l1} ⁵, the receive terminal horizon distance and elevation angle corresponding to the d_i and θ_i with maximum value of θ_i over all equally-spaced points between the transmitter and receiver.

⁵ The units of angles, θ , in this Part are radians.

- 2) Referring to Fig. 1, determine d_{l2} (m) and θ_{l2} , the transmit terminal horizon distance and elevation angle corresponding to the d_i and θ_i with maximum value of θ_i over all equally-spaced points between the receiver and transmitter.
- 3) Determine the elevation of the lunar surface relative to a sphere of radius 1 737 400 m at a set of equidistant points on the lunar surface along the path from the transmit antenna to the receive antenna excluding the region of radius $\min(15 h_{g1}, 0.1 d_{l1})$ m around the transmit antenna and the region of radius $\min(15 h_{g2}, 0.1 d_{l2})$ m around the receive antenna.
- 4) Calculate $d_x = d - d_{l1} - d_{l2}$.
- 5) then, Δh for each representative path is: $\Delta h = \frac{\Delta h(d_x)}{\left(1 - 0.8 e^{-\frac{d_x}{5 \times 10^4}}\right)} \text{ (m)}$.

B.1.1 Preparatory calculations

Define the transmit terminal as $j = 1$ and the receive terminal as $j = 2$. If a terminal is a mobile terminal, then:

$$h_{ej} = h_{gj} \text{ (m)} \quad \text{for } j = 1, 2 \quad (\text{B-7})$$

and, if the terminal is a fixed terminal:

$$B_j = 10 \text{ (m)} \quad \text{for } j = 1, 2 \quad (\text{B-8})$$

in which case,

$$B'_j = (B_j - 1) \sin\left(\frac{\pi}{2} \min\left(\frac{h_{gj}}{5}, 1\right)\right) + 1 \quad (\text{B-9})$$

$B'_j = B_j$ if $h_{gj} \geq 5 \text{ m}$. The effective height of the j^{th} terminal, h_{ej} ($j = 1$ or 2), is then:

$$h_{ej} = h_{gj} + B'_j e^{-\frac{2h_{gj}}{\Delta h}} \quad \text{for } j = 1, 2 \quad (\text{B-10})$$

Calculate the smooth lunar horizon distances, d_{lsj} :

$$d_{lsj} = \sqrt{2h_{ej} a_e} \quad \text{for } j = 1, 2 \text{ (m)} \quad (\text{B-11})$$

The combined smooth lunar radio horizon distance, d_{ls} , the combined irregular terrain radio horizon distance, d_l , and the combined irregular terrain radio horizon elevation angles, θ_e , are then:

$$d_{ls} = d_{ls1} + d_{ls2} \quad (\text{B-12})$$

$$d_l = d_{l1} + d_{l2} \quad (\text{B-13})$$

$$\theta_e = \max(\theta_{e1} + \theta_{e2}, -d_l \gamma_e) \quad (\text{B-14})$$

and $\Delta h(s)$, which is a function of distance, s , is:

$$\Delta h(s) = \Delta h \left(1 - 0.8 e^{-\frac{s}{5 \times 10^4}}\right) \quad (\text{m}) \quad (\text{B-15})$$

B.1.2 Reference attenuation

The reference attenuation, A_{ref} , is the predicted median attenuation relative to free-space that would be observed on similar paths. A_{ref} is the following piecewise function of path horizontal distance, d :

$$A_{ref}(d) = \begin{cases} \max\left[0, A_{el} + K_1 d + K_2 \ln\left(\frac{d}{d_{ls}}\right)\right] & \text{for } d \leq d_{ls} \\ A_{ed} + m_d d & \text{for } d > d_{ls} \end{cases} \quad (\text{dB}) \quad (\text{B-16})$$

where A_{el} is defined in equation (B-72), A_{ed} is defined in equation (B-23), and the coefficients K_1 , K_2 , and m_d are calculated in the following sections. The range $d \leq d_{ls}$ is defined as the line-of-sight range, and the range $d \geq d_{ls}$ is defined as the diffraction range. Note that A_{ref} is continuous at $d = d_{ls}$.

B.1.3 Coefficients for the diffraction range

The coefficients for the diffraction range are calculated by evaluating the diffraction attenuation, $A_{diff}(d)$, at two distances, d_3 and d_4 , which are beyond line-of-sight. Calculate:

$$d_3 = \max(d_{ls}, d_l + 1.3787X_{ae}) \quad (B-17)$$

$$d_4 = d_3 + 2.7574X_{ae} \quad (B-18)$$

$$A_3 = A_{diff}(d_3) \quad (B-19)$$

$$A_4 = A_{diff}(d_4) \quad (B-20)$$

where:

$$X_{ae} = (k\gamma_e^2)^{-\frac{1}{3}} = a_e \left(\frac{2\pi a_e}{\lambda} \right)^{-\frac{1}{3}} \quad (B-21)$$

and the function A_{diff} is defined in equation (B-24).

The parameters m_d and A_{ed} are:

$$m_d = \frac{A_4 - A_3}{d_4 - d_3} \quad \left(\frac{\text{dB}}{\text{m}} \right) \quad (B-22)$$

$$A_{ed} = A_3 - m_d d_3 = \frac{A_3 d_4 - A_4 d_3}{d_4 - d_3} \quad (\text{dB}) \quad (B-23)$$

B.1.4 Diffraction attenuation function

The diffraction attenuation function, $A_{diff}(s)$, is a weighted combination of the ‘double knife-edge’ attenuation, $A_k(s)$, and ‘rounded lunar’ diffraction attenuation, $A_r(s)$:

$$A_{diff}(s) = (1 - w(s))A_k(s) + w(s)A_r(s) \quad (\text{dB}) \quad (B-24)$$

$A_k(s)$ is defined in equation (B-27), $A_r(s)$ is defined in equation (B-37), and the weighting factor, $w(s)$, is defined as:

$$w(s) = \frac{1}{1 + 0.1\sqrt{Q(s)}} \quad (B-25)$$

where:

$$Q(s) = \min\left(\frac{\Delta h(s)}{\lambda}, 1\,000\right) \left[\sqrt{\frac{h_{e1}h_{e2} + C}{h_{g1}h_{g2} + C}} + \frac{d_l + a_e \theta_e}{s} \right] \quad (B-26)$$

and $C = 0$.

The median ‘double knife-edge’ diffraction attenuation for the two irregular lunar radio horizons, $A_k(s)$, is:

$$A_k(s) = Fn(v_1(s)) + Fn(v_2(s)) \quad (\text{dB}) \quad (B-27)$$

where:

$$\begin{aligned} Fn(z) &= -20 \log_{10} \left(\left| \frac{1}{\sqrt{2i}} \int_z^\infty e^{i\frac{\pi}{2}u^2} du \right| \right) \\ &= -20 \log_{10} \left(\left| \frac{1+i}{2\sqrt{2i}} \operatorname{erfc} \left(\frac{\sqrt{\pi}}{2} (1-i)z \right) \right| \right) \end{aligned} \quad (B-28)$$

$$= -20 \log_{10} \left(\left| \frac{1+i}{\sqrt{2}i} Q \left(\sqrt{\frac{\pi}{2}} (1-i)z \right) \right| \right)$$

$$v_j(s) = \frac{\theta(s)}{2} \sqrt{\frac{2d_{lj}(s-d_l)}{\lambda(s-d_l+d_{lj})}} \quad \text{for } j = 1, 2 \quad (\text{B-29})$$

and:

$$\theta(s) = \theta_e + s\gamma_e \quad (\text{B-30})$$

The ‘rounded-lunar’ diffraction attenuation is based on a “three radii” method applied to the solution of the smooth spherical diffraction problem. Calculate γ_0 , γ_1 , and γ_2 as follows:

$$\gamma_0 = \frac{\theta(s)}{s-d_l} \quad (\text{B-31})$$

$$\gamma_j = \frac{2h_{ej}}{d_{lj}^2} \quad \text{for } j = 1, 2 \quad (\text{B-32})$$

Set:

$$\alpha_j = \left(\frac{k}{\gamma_j} \right)^{\frac{1}{3}} \quad \text{for } j = 0, 1, 2 \quad (\text{B-33})$$

and:

$$K_j = \frac{1}{i\alpha_j z_g} \quad \text{for } j = 0, 1, 2 \quad (\text{B-34})$$

Define the dimensionless distances:

$$x_0 = AB(K_0) \alpha_0 \theta(s) + x_1 + x_2 \quad (\text{B-35})$$

and:

$$x_j = AB(K_j) \alpha_j \gamma_j d_{lj} \quad \text{for } j = 1, 2 \quad (\text{B-36})$$

where $A = 63.798$. Note that only x_0 depends on s . The ‘rounded-lunar’ diffraction attenuation, $A_r(s)$, is:

$$A_r(s) = G(x_0) - F(x_1, K_1) - F(x_2, K_2) - C_1(K_0) \quad (\text{dB}) \quad (\text{B-37})$$

where the functions $G(x)$, $F(x, K)$, $C_1(K)$ and $B(K)$ are defined in § B.2.

B.1.5 Coefficients for the line-of-sight range

Set:

$$d_2 = d_{ls} \quad (\text{B-38})$$

and:

$$A_2 = A_{ed} + m_d d_2 \quad (\text{dB}) \quad (\text{B-39})$$

There are two general cases, depending upon the sign of A_{ed} .

Case 1: If $A_{ed} \geq 0$, set:

$$d_0 = \min \left(\frac{d_l}{2}, 1.908 k h_{e1} h_{e2} \right) \quad (\text{B-40})$$

$$d_1 = \frac{3}{4} d_0 + \frac{d_l}{4} \quad (\text{B-41})$$

$$A_0 = A_{los}(d_0) \quad (\text{dB}) \quad (\text{B-42})$$

$$A_1 = A_{los}(d_1) \quad (\text{dB}) \quad (\text{B-43})$$

Calculate:

$$K'_2 = \max\left(0, \frac{(A_1 - A_0)(d_2 - d_0) - (A_2 - A_0)(d_1 - d_0)}{(d_2 - d_0) \ln\left(\frac{d_1}{d_0}\right) - (d_1 - d_0) \ln\left(\frac{d_2}{d_0}\right)}\right) \quad (\text{B-44})$$

and:

$$K'_1 = \frac{A_2 - A_0 - K'_2 \ln\left(\frac{d_2}{d_0}\right)}{d_2 - d_0} \quad (\text{B-45})$$

If $K'_1 \geq 0$, set:

$$K_1 = K'_1 \quad (\text{B-46})$$

$$K_2 = K'_2 \quad (\text{B-47})$$

However, if $K'_1 < 0$, set:

$$K''_2 = \frac{A_2 - A_0}{\ln\left(\frac{d_2}{d_0}\right)} \quad (\text{B-48})$$

If $K''_2 \geq 0$, set:

$$K_1 = 0 \quad (\text{B-49})$$

$$K_2 = K''_2 \quad (\text{B-50})$$

However, if $K''_2 < 0$, set:

$$K_1 = m_d \quad (\text{B-51})$$

$$K_2 = 0 \quad (\text{B-52})$$

Case 2: If $A_{ed} < 0$, set:

$$d_0 = 1.908 k h_{e1} h_{e2} \quad (\text{B-53})$$

$$d_1 = \max\left(-\frac{A_{ed}}{m_d}, \frac{d_l}{4}\right) \quad (\text{B-54})$$

If $d_0 < d_1$, set:

$$A_0 = A_{los}(d_0) \quad (\text{dB}) \quad (\text{B-55})$$

$$A_1 = A_{los}(d_1) \quad (\text{dB}) \quad (\text{B-56})$$

and:

$$K'_2 = \max\left(0, \frac{(A_1 - A_0)(d_2 - d_0) - (A_2 - A_0)(d_1 - d_0)}{(d_2 - d_0) \ln\left(\frac{d_1}{d_0}\right) - (d_1 - d_0) \ln\left(\frac{d_2}{d_0}\right)}\right) \quad (\text{B-57})$$

If $K'_2 \neq 0$, calculate:

$$K'_1 = \frac{A_2 - A_0 - K'_2 \ln\left(\frac{d_2}{d_0}\right)}{d_2 - d_0} \quad (\text{B-58})$$

If $K'_1 \geq 0$, set:

$$K_1 = K'_1 \quad (\text{B-59})$$

$$K_2 = K'_2 \quad (\text{B-60})$$

If $K'_1 < 0$, set:

$$K''_2 = \frac{A_2 - A_0}{\ln\left(\frac{d_2}{d_0}\right)} \quad (\text{B-61})$$

If $K''_2 \geq 0$, then:

$$K_1 = 0 \quad (\text{B-62})$$

$$K_2 = K''_2 \quad (\text{B-63})$$

If $K''_2 < 0$, then:

$$K_1 = m_d \quad (\text{B-64})$$

$$K_2 = 0 \quad (\text{B-65})$$

If $d_0 \geq d_1$ or $K'_2 = 0$, then:

$$A_1 = A_{los}(d_1) \quad (\text{dB}) \quad (\text{B-66})$$

$$K''_1 = \frac{A_2 - A_1}{d_2 - d_1} \quad (\text{B-67})$$

If $K''_1 > 0$, then:

$$K_1 = K''_1 \quad (\text{B-68})$$

$$K_2 = 0 \quad (\text{B-69})$$

Otherwise, set:

$$K_1 = m_d \quad (\text{B-70})$$

$$K_2 = 0 \quad (\text{B-71})$$

Finally, set:

$$A_{el} = A_2 - K_1 d_2 \quad (\text{dB}) \quad (\text{B-72})$$

B.1.6 The line-of-sight range attenuation function

The line-of-sight range attenuation function, $A_{los}(s)$, is the weighted combination of the “extrapolated/extended diffraction range” attenuation, $A_d(s)$, and the “two-ray” attenuation, $A_t(s)$:

$$A_{los}(s) = (1 - w)A_d(s) + wA_t(s) \quad (\text{dB}) \quad (\text{B-73})$$

$A_d(s)$ is defined in equation (B-75), $A_t(s)$ is defined in equation (B-82), and the weighting function, w , is:

$$w = \frac{1}{1 + \frac{D_1 k \Delta h}{\max(D_2, d_{ls})}} \quad (\text{B-74})$$

where $D_1 = 47.7$ m, and $D_2 = 10$ km. The “extended diffraction range” attenuation is:

$$A_d(s) = A_{ed} + m_d s \quad (\text{B-75})$$

For the “two-ray” attenuation, set:

$$\sin \psi(s) = \frac{h_{e1} + h_{e2}}{\sqrt{s^2 + (h_{e1} + h_{e2})^2}} \quad (\text{B-76})$$

and:

$$R'_e(s) = \frac{\sin \psi(s) - Z_g}{\sin \psi(s) + Z_g} e^{-k \sigma_h(s) \sin \psi(s)} \quad (\text{B-77})$$

where:

$$\sigma_h(s) = \frac{\Delta h(s)}{1.282} e^{-\frac{4\sqrt{\Delta h(s)}}{2}} \quad (\text{B-78})$$

Set:

$$\delta'(s) = 2 \frac{kh_{e1}h_{e2}}{s} \quad (\text{B-79})$$

The effective reflection coefficient, $R_e(s)$, is:

$$R_e(s) = \begin{cases} R'_e(s) & \text{for } |R'_e(s)| \geq \max(0.5, \sqrt{\sin \psi(s)}) \\ \frac{R'_e(s)}{|R'_e(s)|} \sqrt{\sin \psi(s)} & \text{otherwise} \end{cases} \quad (\text{B-80})$$

The phase difference, $\delta(s)$, is:

$$\delta(s) = \begin{cases} \delta'(s) & \text{for } \delta'(s) \leq \frac{\pi}{2} \\ \pi - \frac{(\frac{\pi}{2})^2}{\delta'(s)} & \text{otherwise} \end{cases} \quad (\text{B-81})$$

The “two-ray” attenuation, $A_t(s)$, is then:

$$A_t(s) = -20 \log_{10} |1 + R_e(s)e^{i\delta(s)}| \quad (\text{dB}) \quad (\text{B-82})$$

B.1.7 Location variability

$A_{ref}(p)$, the attenuation relative to free-space that is not exceeded for the fraction of equivalent terrain profiles, p ($0 < p < 1$) is calculated as follows:

Calculate $\Delta h(d)$, σ , and z as follows, where d is the entire path length:

$$\Delta h(d) = \Delta h \left(1 - 0.8 e^{-\frac{d_x}{5 \times 10^4}} \right) \quad (\text{B-83})$$

$$\sigma = \frac{10 k \Delta h(d)}{k \Delta h(d) + 13} \quad (\text{B-84})$$

$$z = Q^{-1}(p) \quad (\text{B-85})$$

where d is the entire path length.

Then:

$$A_{ref}(p) = A_{ref} + \sigma z \quad (\text{dB}) \quad (\text{B-86})$$

B.2 Functions $G(x)$, $F(x, K)$, $C_1(K)$ and $B(K)$

$$F(x, K) = \begin{cases} F_2(x, K), & \text{for } 0 < x \leq 200 \\ G(x) + 0.013x e^{-\frac{x}{200}} [F_1(x) - G(x)], & \text{for } 200 < x < 2\,000 \\ G(x), & \text{for } x \geq 2\,000 \end{cases} \quad (\text{B-87})$$

where:

$$G(x) = 0.05751 x - 10 \log_{10} x \quad (\text{B-88})$$

$$F_1(x) = 40 \log_{10}(\max(x, 1)) - 117 \quad (\text{B-89})$$

$$F_2(x, K) = \begin{cases} F_1(x) & \text{for } |K| < 10^{-5} \text{ or } x(-\log_{10}|K|)^3 > 450 \\ 2.5 x \frac{10^{-5}x^2}{|K|} + 20 \log_{10}(|K|) - 15 & \text{otherwise} \end{cases} \quad (\text{B-90})$$

$$C_1(K) = 20 \quad (B-91)$$

$$B(K) = 1.607 - |K| \quad (B-92)$$

PART C

Electrical characteristics of the surface of the Moon**C.1 Regolith complex relative permittivity****C.1.1 Inputs to regolith complex relative permittivity**

The regolith complex relative permittivity requires the following parameters:

- Regolith depth
- Regolith content of titanium oxide (TiO₂) and ferrous oxide (FeO) minerals
- Regolith bulk density (specific gravity, porosity, void ratio)
- Regolith temperature
- RF frequency

C.1.2 Regolith depth

The regolith depth, d , is calculated as follows:

$$d = 9.5 + 8.5 \tanh\left(\frac{H+1200}{1632.5}\right) \quad (\text{m}) \quad (\text{C-1})$$

where, H , is the elevation in metres. For reference, the digital elevation of the lunar surface is shown in Fig. 2. Digital lunar elevation maps at various projections, resolutions, and formats are available from https://imbrium.mit.edu/DATA/LOLA_GDR/

Lunar latitude and longitude are defined in the Mean Earth/polar axis (ME) selenographic coordinate system. The lunar Z-axis is the mean rotation axis of the Moon, and the +Z axis points toward the lunar North pole; the lunar equator, defined by the XY-plane, is perpendicular to the Z-axis and intersects the Z-axis at the Moon's centre of mass; the lunar prime meridian, defined by the X-axis, points in the mean Earth direction as seen from the Moon (i.e. the mean sub-Earth point on the lunar surface); and the Y-axis completes the right-handed coordinate system.

FIGURE 2
Elevation map of the lunar surface (km)

C.1.3 Mineral content

The lunar regolith permittivity is a function of the percentages of titanium oxide (TiO_2) and ferrous oxide (FeO). For reference, the lunar percentages of FeO and TiO_2 between 60° N and 60° S are shown in Figs 3 and 4. High resolution maps of FeO and TiO_2 are available at <https://zenodo.org/records/7263426> and <https://zenodo.org/records/7264329>, respectively.

C.1.4 Bulk density

The bulk density, ρ , of a material is the mass of the material contained within a given volume, usually expressed in grams per cubic centimetre (g/cm^3). The porosity, and specific gravity are other parameters related to the bulk density. The porosity, ϕ , is defined as the volume of void space between the particles divided by the total volume. The specific gravity, G , of a soil particle is the ratio of its mass to the mass of an equal volume of water at 4 °C. Many lunar soils have a specific gravity of 2.7; i.e. the density of the individual particles is $2.7 \text{ g}/\text{cm}^3$, or 2.7 times that of water ρ_w ($1 \text{ g}/\text{cm}^3$). The volume fraction, V , is the ratio of the volume of soil particles over the total volume. Bulk density, porosity, specific gravity, and volume fraction are interrelated as:

$$\rho_{reg} = G \rho_w (1 - \phi) \quad (\text{C-2})$$

$$V = 1 - \phi \quad (\text{C-3})$$

The regolith bulk density, $\rho_{reg}(z)$, varies with regolith depth, z (m) as follows:

$$\rho_{reg}(z) = 1.890 \frac{0.0169 - z}{0.0290 - z}, \quad \frac{\text{g}}{\text{cm}^3} \quad (\text{C-4})$$

where the minus sign on the depth axis is not shown. Figure 5 shows the trend of bulk density vs. regolith depth.

P.2170-05

C.1.5 Temperature

The temperature of the lunar regolith varies with lunar latitude and longitude and lunar time. However, the complex relative permittivity of the lunar regolith is independent of temperature at frequencies between 1 MHz and 37 GHz.

C.1.6 Regolith complex relative permittivity at frequencies between 1 MHz and 37 GHz

At frequencies between 1 MHz and 37 GHz, the regolith complex relative permittivity, ϵ_{reg} , is:

$$\epsilon_{reg} = \epsilon'_{reg} - i \epsilon''_{reg} = \epsilon'_{reg} - i \epsilon'_{reg} \tan \delta \quad (C-5)$$

The real part of the regolith complex relative permittivity, ϵ'_{reg} , is a function of bulk density, ρ_{reg} , and is independent of frequency and temperature:

$$\epsilon'_{reg} = 1.919 \rho_{reg} \quad (C-6)$$

The loss tangent, $\tan \delta_{reg}$, is a function of frequency (GHz), bulk density, and percentages of TiO_2 and FeO :

$$\tan \delta_{reg} = 10^{\{(a_1 f_{\text{GHz}} + a_2) \rho_{reg} + b_1 S - b_2\}} \quad (C-7)$$

where the coefficients a_1 , a_2 , b_1 , b_2 and S are as follows:

$$a_1 = 0.0272 \text{ GHz}^{-1}$$

$$a_2 = 0.2967$$

$$b_1 = 0.027$$

$$b_2 = 3.058$$

$$S = \% \text{TiO}_2 + \% \text{FeO}.$$

Since the density, ρ , is a function of regolith thickness (see equation (C-1)), the regolith complex relative permittivity is also a function of regolith depth. Figures 6 and 7 show examples of the real part of the complex relative permittivity and the loss tangent vs. regolith depth for contents of TiO_2 and FeO contents of 4% and 15%, respectively, and a typical regolith thickness of 2 m.

FIGURE 6

Real part of regolith permittivity for frequencies above 1 MHz as a function of regolith depth ($d = 2 \text{ m}$)

FIGURE 7

The regolith loss tangent at 1.5 GHz vs. regolith depth ($\text{TiO}_2 = 4\%$, and $\text{FeO} = 15\%$, $d = 2 \text{ m}$)

P.2170-07

C.2 Lunar rock complex relative permittivity

Similarly to the regolith complex relative permittivity, the lunar rock complex relative permittivity ϵ_{rock} :

$$\epsilon_{rock} = \epsilon'_{rock} - i \epsilon'_{rock} \tan \delta_{rock} \quad (\text{C-8})$$

Similarly to the regolith complex relative permittivity, the real part of the lunar rock complex permittivity is:

$$\epsilon'_{rock} = 1.919 \rho_{rock} \quad (\text{C-9})$$

While there is no current empirical or theoretical model of lunar rock density, typical rock densities are between 2 and 3.3 g cm^{-3} , in which case, ϵ'_{rock} varies between 3.626 and 8.593 .

The loss tangent, $\tan \delta_{rock}$, is a function of frequency (GHz), bulk density, percentages of TiO_2 and FeO , the dc conductivity, σ_{rock} , and the real part of the lunar rock complex relative permittivity as follows:

$$\tan \delta_{rock} = 10^{\{(a_1 f_{\text{GHz}} + a_2) \rho_{rock} + b_1 S - b_2\}} + \frac{17.984 \sigma_{rock}}{\epsilon'_{rock} f_{\text{GHz}}} \quad (\text{C-10})$$

where:

$$\sigma_{rock} = 3 \times 10^{-14} e^{0.0230T}, \text{ mho/m} \quad (\text{C-11})$$

and the coefficients a_1 , a_2 , b_1 , b_2 and S are:

$$a_1 = 0.0086 \text{ GHz}^{-1}$$

$$a_2 = 0.1833$$

$$b_1 = 0.038$$

$$b_2 = 3.26$$

$$S = 11\%$$

C.3 Lunar regolith complex relative permeability

The real and imaginary parts of the lunar regolith magnetic permeability at frequencies above 300 MHz are:

$$\mu'_r = 1 \quad (\text{C-12})$$

$$\mu''_r = 0 \quad (\text{C-13})$$

C.4 Complex relative permittivity of regolith and rock mixture

When there is a mixture of rock and regolith, by treating the rock particles as spherical particles, the equivalent complex relative permittivity of the mixture, $\epsilon_{mixture}$, is:

$$\epsilon_{mixture} = \frac{-B + \sqrt{B^2 - 4AC}}{2A} \quad (\text{C-14})$$

where:

$$A = 2 \quad (\text{C-15})$$

$$B = -2(1 - V_{rock})\epsilon_{reg} + (1 - 3V_{rock})\epsilon_{rock} \quad (\text{C-16})$$

$$C = -\epsilon_{reg}\epsilon_{rock} \quad (\text{C-17})$$

and V_{rock} is the rock volume fraction. In the absence of local data, $V_{rock} = 0$ can be assumed, in which case $\epsilon_{mixed} = \epsilon_{reg}$.

PART D

Prediction of other propagation losses

D.1 Free-space propagation loss

It is recommended that the free-space propagation loss specified in § 2.3 of Recommendation ITU-R P.525 be used between: a) systems on or near the lunar surface and systems in lunar orbit, b) systems on or near the lunar surface and systems orbiting the Earth, and c) system in lunar orbit and systems orbiting the Earth, where the line-of-sight path is unobstructed and there are no reflections.

D.2 Propagation loss considering the atmosphere of the Earth

The propagation loss between: a) systems on or near the surface of the Moon or in lunar orbit, and b) systems on or near the surface of the Earth or in Earth orbit, where the line-of-sight path is unobstructed and there are no reflections should be calculated as the sum of a) the free-space propagation loss specified in § 2.3 of Recommendation ITU-R P.525, and b) the applicable atmospheric propagation losses specified in § 2 of Recommendation ITU-R P.618.
