# Recommendation ITU-T G.107.1

## Wideband E-model

### Corrigendum 1

#### Summary

Recommendation ITU-T G.107.1 gives the algorithm for the wideband (WB) version of the E-model as the common ITU-T transmission rating model for planning speech services that provide WB speech transmission (50-7000 Hz). This computational model can be useful to transmission planners, to help ensure that users will be satisfied with end-to-end transmission performance. The primary output of the model is a scalar rating of transmission quality. A major feature of this model is the use of transmission impairment factors that reflect the effects of different types of degradations occurring on the entire transmission path, mouth-to-ear.

Corrigendum 1 corrects Equation (7-6).

## FOREWORD

The International Telecommunication Union (ITU) is the United Nations specialized agency in the field of telecommunications, information and communication technologies (ICTs). The ITU Telecommunication Standardization Sector (ITU-T) is a permanent organ of ITU. ITU-T is responsible for studying technical, operating and tariff questions and issuing Recommendations on them with a view to standardizing telecommunications on a worldwide basis.

The World Telecommunication Standardization Assembly (WTSA), which meets every four years, establishes the topics for study by the ITU-T study groups which, in turn, produce Recommendations on these topics.

The approval of ITU-T Recommendations is covered by the procedure laid down in WTSA Resolution 1.

In some areas of information technology which fall within ITU-T's purview, the necessary standards are prepared on a collaborative basis with ISO and IEC.

## NOTE

In this Recommendation, the expression "Administration" is used for conciseness to indicate both a telecommunication administration and a recognized operating agency.

Compliance with this Recommendation is voluntary. However, the Recommendation may contain certain mandatory provisions (to ensure, e.g., interoperability or applicability) and compliance with the Recommendation is achieved when all of these mandatory provisions are met. The words "shall" or some other obligatory language such as "must" and the negative equivalents are used to express requirements. The use of such words does not suggest that compliance with the Recommendation is required of any party.

## INTELLECTUAL PROPERTY RIGHTS

ITU draws attention to the possibility that the practice or implementation of this Recommendation may involve the use of a claimed Intellectual Property Right. ITU takes no position concerning the evidence, validity or applicability of claimed Intellectual Property Rights, whether asserted by ITU members or others outside of the Recommendation development process.

As of the date of approval of this Recommendation, ITU had not received notice of intellectual property, protected by patents, which may be required to implement this Recommendation. However, implementers are cautioned that this may not represent the latest information and are therefore strongly urged to consult the TSB patent database at <http://www.itu.int/ITU-T/ipr/>.

# Recommendation ITU-T G.107.1

## Wideband E-model

### Corrigendum 1

*Editorial note: This is a complete-text publication. Modifications introduced by this corrigendum are shown in revision marks relative to Recommendation ITU-T G.107.1 (2019)*

#### 1 Scope

This Recommendation describes the wideband (WB) version of a computational model, known as the E-model, that has proven useful as a transmission planning tool for assessing the combined effects of variations in several transmission parameters that affect conversational<sup>1</sup> quality. This computational model can be used, for example, by transmission planners to help ensure that users will be satisfied with end-to-end transmission performance whilst avoiding over-engineering of networks. It must be emphasized that the primary output from the model is the "rating factor" *R*, but this can be transformed to give estimates of customer opinion. Such estimates are only made for transmission planning purposes and not for actual customer opinion prediction (for which there is no agreed-upon model recommended by the ITU-T).

This version is an adapted version of the NB (300-3400 Hz) E-model, typically referred to as "the E-model", which is described in [ITU-T G.107]. The WB version addresses scenarios which include WB (50-7000 Hz) transmission. It does not replace the narrowband (NB) E-model. Instead, it describes a separate WB-version of the model that uses, within limits, similar concepts and input parameters as the NB E-model. The current version captures the effects of talker echo, absolute delay, WB speech coding, and voice-over-IP packet-loss. Degradations which are covered but have not yet been studied in detail are listener echo. Degradations which are not yet covered are loudness loss, non-optimum sidetone levels, background noise at the sending and receiving side, circuit noise and quantizing distortions.

For many parameter combinations of high importance to transmission planners, ITU-T G.107.1 can be used with confidence (e.g., loudness loss, coding distortions), but for some parameter combinations of high importance (e.g., the effects of delay in conjunction with other impairments), WB E-model predictions have been questioned and are currently under study.

Regarding the interpretation of the WB E-model ratings, note that the current versions of [b-ITU-T G.108], [b-ITU-T G.108.1] and [b-ITU-T G.109] do not refer to the WB version described here, but only to the NB version of the E-model described in [ITU-T G.107].

## 6 WB E-model

### 6.1 Introduction

The complexity of modern networks requires that, for transmission planning, the many transmission parameters be not only considered individually, but also that their combined effects be taken into account. This can be done by "expert, informed guessing", but a more systematic approach is desirable, such as by using a computational model. The output from the model described here is a scalar transmission rating value,  $R$ , which varies directly with the overall conversational quality. [ITU-T G.113] gives guidance about specific impairments, including combined effects based upon a simplification of the model.

### 6.2 Transmission rating scale of the WB E-model

For the narrowband (NB) case described in [ITU-T G.107], the transmission rating scale ranges from  $R = 0$  (lowest possible quality) to  $R = 100$  (optimum quality). On this scale, a default NB transmission channel including logarithmic Pulse Code Modulation (PCM) coding and a noise floor (default parameter values according to Table 2 of [ITU-T G.107]) obtains a rating of  $R = 93.2$ . For a WB speech transmission channel, the quality is generally judged better than that for a NB channel. Thus, this scale range was extended in order to be also applicable to WB transmission scenarios. In the present WB version, the E-model is defined for a WB transmission channel of 50-7000 Hz, as it is defined in [ITU-T G.722].

Unfortunately, it is not possible to obtain direct human judgements on the  $R$ -scale, as this scale has additivity properties which are not reflected by ordinary rating scales. Instead, for NB conditions, ITU-T recommends collecting judgements on a 5-point absolute category rating scale, see [ITU-T P.800]. The mean rating, averaged over all test participants and stimuli reflecting the same circuit condition, is then called a mean opinion score (MOS).

It has been shown that MOS ratings differ between tests where only NB stimuli are presented and tests where both NB/WB or purely WB stimuli are presented, as the use of the scale is largely influenced by the stimulus set. On the other hand, there is also experimental evidence that judgements for WB samples collected in a purely WB context do not differ significantly from those collected in a mixed NB/WB context, see [b-Barriac] and [b-Takahashi]. In addition to the stimulus bandwidth, test results are influenced by the test participant group, the language, the participants' native country, etc. [b-Möller-01]. For a NB context, an average S-shaped relationship is defined between the  $R$ -scale (range [0;100]) and MOS ratings (range [1;4.5]) collected from "average" test participants in an "average" experimental setting, see Annex B and Appendix I of [ITU-T G.107].

For a WB or a mixed NB/WB context, the  $R$ -scale was extended in a way which leaves the NB use of the scale unaffected, including the position of the reference connection (default parameter settings according to Table 2 of [ITU-T G.107]). Such an extension can be based on pairs of auditory tests in which the same (NB) test stimuli have been judged once in a purely NB and once in a mixed NB/WB

context. The judgements on these common stimuli define a relationship between the use of the MOS-scale in a NB and in a mixed NB/WB context [b-Raake-01].

Two pairs of tests have been carried out and will be considered in the following. Details on parts of the tests can be found in [b-Möller-02]. The MOS results from these tests have been transformed to the  $R$ -scale using the NB transformation rule given in Annex B of [ITU-T G.107]. The resulting  $R_{NB}$  values (NB test) and  $R_{NB/WB}$  values (mixed NB/WB test) for the conditions which were common in each pair are displayed in Figure 1.

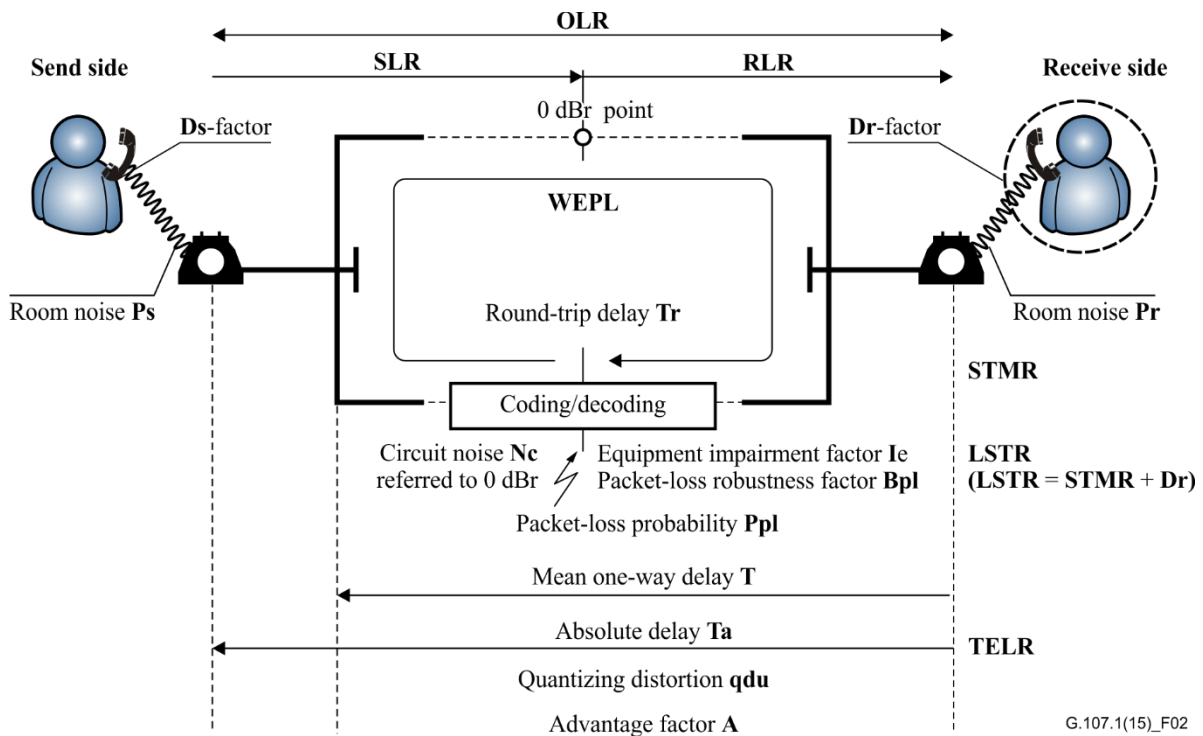

**Figure 1 – Comparison between  $R$ -values derived in a NB and in a mixed NB/WB context**

Due to the use of the NB relationship between MOS and  $R$  for deriving the  $R_{NB/WB}$  values, the maximum  $R_{NB/WB}$  value corresponding to MOS = 4.5 equals 100. The corresponding  $R_{NB}$  value of the panels in Figure 1 shows the amount by which the  $R$ -scale has to be extended in a NB/WB context. This maximum value is around  $R_{max} = 129$ . In other words, the NB transmission rating scale of the E-model has been extended by approximately 29% to reflect the quality improvement when migrating from NB to WB. This extended  $R$ -scale is a "universal"  $R$ -scale and it is applicable to both NB and WB transmission channels.

The primary output of the WB E-model is the transmission rating  $R$ . However, the output can also give nominal estimates of user reactions, for instance in the form of MOS values, as described in Annex A.

## 7 The structure and basic algorithms of the WB E-model

The WB E-model is based on the equipment impairment factor method, following previous transmission rating models. The reference connection, as shown in Figure 2, is split into a send side and a receive side. The model estimates the conversational quality from mouth-to-ear as perceived by the user at the receive side, both as listener and talker.

**Figure 2 – Reference connection of the WB E-model**

The transmission parameters used as an input to the computation model are shown in Figure 2. Values for room noise and for the  $D$ -factors are handled separately in the algorithm for the send side and receive side and may be of different amounts. The parameters send loudness rating (SLR), receive loudness rating (RLR) and circuit noise  $N_c$  are referred to a defined 0 dBr point. All other input parameters are either considered as values for the overall connection, such as overall loudness rating (OLR) (in any case, the sum of SLR and RLR), equipment impairment factors  $I_e$  and advantage factor  $A$ , or referred to only for the receive side, such as sidetone masking rating (STMR), LSTR, weighted echo pass loss (WEPL) (for calculation of listener echo) and talker echo loudness rating (TELR).

There are three different parameters associated with transmission time. The absolute delay  $T_a$  represents the total one-way delay between the send side and receive side and is used to estimate the impairment due to excessive delay. The parameter mean one-way delay  $T$  represents the delay between the receive side (in talking state) and the point in a connection where a signal coupling occurs as a source of echo. The round-trip delay  $T_r$  only represents the delay in a 4-wire loop, where the "double reflected" signal will cause impairments due to listener echo.

Not all parameters listed in Figure 2 are currently used in the WB E-model. However, they are displayed here in order to provide a full description of the transmission channel considering also degradations which might be included in an updated WB E-model at a later stage. The current version

is based on [b-Raake-02] and on further extensions for talker echo and delay which have been presented in ITU's Telecommunication Sector (ITU-T).

### 7.1 Calculation of the transmission rating factor, $R$

For WB, the basic E-model formula (7-1 of [ITU-T G.107]) can be re-written as:

$$R = Ro, WB - Is, WB - Id, WB - Ie, eff, WB + A \quad (7-1)$$

$Ro, WB$  represents in principle the basic signal-to-noise ratio, including noise sources such as circuit noise and room noise. Factor  $Is, WB$  is a combination of all impairments which occur more or less simultaneously with the voice signal. Factor  $Id, WB$  represents the impairments caused by delay and the effective equipment impairment factor  $Ie, eff, WB$  represents impairments caused by low bit-rate codecs. It also includes impairment due to randomly distributed pack losses. The advantage factor  $A$  allows for compensation of impairment factors when the user benefits from other types of access. The term  $Id, WB$  is subdivided into further specific impairment values. The following clauses give the equations used in the WB E-model.

### 7.2 Basic signal-to-noise ratio, $Ro, WB$

The basic signal-to-noise ratio  $Ro, WB$  is defined by:

$$Ro, WB = 129 \quad (7-2)$$

The effects of circuit noise  $Nc$ , room noise at send side  $Ps$  and room noise at receive side  $Pr$  are items for further study.

### 7.3 Simultaneous impairment factor, $Is, WB$

The factor  $Is, WB$  is the sum of all impairments which may occur more or less simultaneously with the voice transmission. This aspect has not been analysed for the WB case so far, thus it is set to:

$$Is, WB = 0 \quad (7-3)$$

### 7.4 Delay impairment factor, $Id, WB$

$Id, WB$ , the impairment factor representing all impairments due to delay of voice signals, is further divided into the three factors  $Idte, WB$ ,  $Idle, WB$  and  $Idd$ :

$$Id, WB = Idte, WB + Idle, WB + Idd \quad (7-4)$$

The factor  $Idte, WB$  gives an estimate for the impairments due to talker echo:

$$Idte, WB = \left[ \frac{Roe - Re, WB}{2} + \sqrt{\frac{(Roe - Re, WB)^2}{4} + 100} - 1 \right] (1 - e^{-T}) \quad (7-5)$$

where:

$$\text{~~Roe = -1.5(No, WB - RLR)~~ } Roe = -1.5(-69 - RLR) \quad (7-6)$$

$$Re, WB = 80 + 3(TERV, WB - 14) \quad (7-7)$$

$$TERV, WB = TELR + K - 40 \log \frac{1 + \frac{T}{10}}{1 + \frac{T}{150}} + 6e^{-0.3T^2} \quad (7-8)$$

For  $T < 100$  ms:

$$K = 0.08 \cdot T + 10 \quad (7-9)$$

For  $T \geq 100$  ms:

$$K = 18 \quad (7-10)$$

For the WB case, we currently do not assume any mutual influence between talker echo and sidetone.

The factor  $Idle, WB$  represents impairments due to listener echo. This impairment has not been specifically studied for the WB case, but it is assumed that the degradations will be similar to those of the NB case, so the formulae are congruent with the ones of the NB E-model:

$$Idle, WB = \frac{Ro, WB - Rle}{2} + \sqrt{\frac{(Ro, WB - Rle)^2}{4} + 169} \quad (7-11)$$

where:

$$Rle = 10.5(WEPL + 7)(Tr + 1)^{-0.25} \quad (7-12)$$

The factor  $Idd$  represents the impairment caused by an absolute delay  $Ta$  that is too long, which occurs even with perfect echo cancelling.

For  $Ta \leq 100$  ms:

$$Idd = 0$$

For  $Ta > 100$  ms:

$$Idd = 25 \cdot 1.29 \left\{ (1 + X^6)^{\frac{1}{6}} - 3 \left( 1 + \left[ \frac{X}{3} \right]^6 \right)^{\frac{1}{6}} + 2 \right\} \quad (7-13)$$

with:

$$X = \frac{\log\left(\frac{Ta}{100}\right)}{\log 2} \quad (7-14)$$

## 7.5 Equipment impairment factor, $Ie, WB$

The values for the equipment impairment factor  $Ie, WB$  of elements using low bit-rate codecs are not related to other input parameters. They depend on subjective MOS test results as well as on network experience. Refer to Appendix IV of [ITU-T G.113] for the currently recommended values of  $Ie, WB$ .

In case of packet-loss, the packet-loss dependent effective equipment impairment factor  $Ie, eff, WB$  is derived using the codec-specific value for the equipment impairment factor at zero packet-loss  $Ie, WB$  and the packet-loss robustness factor  $Bpl$ . With the packet-loss probability  $Ppl$ ,  $Ie, eff, WB$  is calculated using the equation:

$$Ie, effWB = IeWB + (95 - Ie, WB) \cdot \frac{Ppl}{Ppl + Bpl} \quad (7-15)$$

As can be seen from Equation 7-15, the effective equipment impairment factor in case of  $Ppl = 0$  (no packet-loss) is equal to the  $Ie, WB$  value defined in Appendix IV of [ITU-T G.113].

Corresponding values for  $Bpl, wb$  can be found in Appendix IV of [ITU-T G.113].

One should derive  $Ie-effWB$  by using the  $Ie, wb$  and  $Bpl$  values if they are provided in [ITU-T G.113]. If, for practical reasons, it is difficult to observe the packet-loss rate ( $Ppl$ ), one can use the approach found in [ITU-T P.834.1] to directly derive  $Ie-effWB$ .

If  $Ie, wb$  is derived directly by using the instrumental method recommended in [ITU-T P.834.1], it already reflects the effect of packet-loss introduced in the preparation of speech materials under test.

Therefore, one should not use equation (7-15). Rather, one should use the  $I_{e,wb}$  value derived by [ITU-T P.834.1] in  $I_{e-effWB}$  in equation (7-1).

## 7.6 Advantage factor, $A$

Background information on the advantage factor  $A$  can be found in Appendix II of [ITU-T G.113]. As this effect has not yet been studied for the WB case, it is recommended to set:

$$A = 0 \quad (7-16)$$

## 7.7 Default values

For all input parameters used in the algorithm of the E-model, the default values are listed in Table 1. It is strongly recommended to use these default values for all parameters which are not varied during planning calculation.

**Table 1 – Default values and permitted ranges for the parameters**

Parameter	Abbr.	Unit	Default value	Permitted range	Remark
Send loudness rating	SLR	dB	+8	-	(Note 3)
Receive loudness rating	RLR	dB	+2	-	(Note 3)
Sidetone masking rating	STMR	dB	15	10 ... 20	(Note 2)
Listener sidetone rating	LSTR	dB	18	13 ... 23	(Note 2)
D-Value of telephone, send side	Ds	–	3	-	(Note 3)
D-Value of telephone, receive side	Dr	–	3	-	(Note 3)
Talker echo loudness rating	TELR	dB	65	5 ... 65	
Weighted echo path loss	WEPL	dB	110	5 ... 110	
Mean one-way delay of the echo path	T	ms	0	0 ... 500	
Round-trip delay in a 4-wire loop	Tr	ms	0	0 ... 1000	
Absolute delay in echo-free connections	Ta	ms	0	0 ... 500	
Equipment impairment factor	$I_{e,WB}$	–	0	0 ... 56	(Note 4)
Packet-loss robustness factor	Bpl	–	4.3	4.3 ... 7.3	(Notes 3, 4)
Random packet-loss probability	Ppl	%	0	0 ... 20	(Notes 3, 4)
Circuit noise referred to 0 dBr-point	Nc	dBm0p	–70	-	(Note 3)
Noise floor at the receive side	Nfor	dBmp	–96	–	(Note 3)
Room noise at the send side	Ps	dB(A)	35	-	(Note 3)
Room noise at the receive side	Pr	dB(A)	35	-	(Note 3)
Advantage factor	A	–	0	0 ... 20	
NOTE 1 – Total values between microphone or receiver and 0 dBr-point. NOTE 2 – Fixed relation: $LSTR = STMR + D$ . NOTE 3 – Currently under study. NOTE 4 – If $Ppl > 0\%$ , then the Bpl must match the codec, packet size, and PLC assumed.					

## Annex A

### MOS values derived from the transmission rating factor $R$

(This annex forms an integral part of this Recommendation.)

The transmission rating factor  $R$  can be in the range from 0 to 129, where  $R = 0$  represents an extremely bad quality and  $R = 129$  represents a very high quality in the WB case. An estimated mean opinion score ( $\text{MOS}_{\text{CQEW}}$ ) for the conversational situation on the scale 1-5 can be obtained from the  $R$ -factor by using the equations:

$$Rx = \frac{R}{1.29} \quad (\text{A-1})$$

$$\text{For } Rx < 0: \quad \text{MOS}_{\text{CQEW}} = 1$$

$$\text{For } 0 < Rx < 100: \quad \text{MOS}_{\text{CQEW}} = 1 + 0.035 Rx + Rx(Rx - 60)(100 - Rx)7 \cdot 10^{-6} \quad (\text{A-2})$$

$$\text{For } Rx > 100: \quad \text{MOS}_{\text{CQEW}} = 4.5$$

## SERIES OF ITU-T RECOMMENDATIONS

Series A	Organization of the work of ITU-T
Series D	Tariff and accounting principles and international telecommunication/ICT economic and policy issues
Series E	Overall network operation, telephone service, service operation and human factors
Series F	Non-telephone telecommunication services
<b>Series G</b>	<b>Transmission systems and media, digital systems and networks</b>
Series H	Audiovisual and multimedia systems
Series I	Integrated services digital network
Series J	Cable networks and transmission of television, sound programme and other multimedia signals
Series K	Protection against interference
Series L	Environment and ICTs, climate change, e-waste, energy efficiency; construction, installation and protection of cables and other elements of outside plant
Series M	Telecommunication management, including TMN and network maintenance
Series N	Maintenance: international sound programme and television transmission circuits
Series O	Specifications of measuring equipment
Series P	Telephone transmission quality, telephone installations, local line networks
Series Q	Switching and signalling, and associated measurements and tests
Series R	Telegraph transmission
Series S	Telegraph services terminal equipment
Series T	Terminals for telematic services
Series U	Telegraph switching
Series V	Data communication over the telephone network
Series X	Data networks, open system communications and security
Series Y	Global information infrastructure, Internet protocol aspects, next-generation networks, Internet of Things and smart cities
Series Z	Languages and general software aspects for telecommunication systems
