Recommendation ITU-T J.249

Recommendation ITU-T J.249

Perceptual video quality measurement techniques for digital cable television in the presence of a reduced reference

Summary

Recommendation ITU-T J.249 provides guidelines on the selection of appropriate objective perceptual video quality measurement methods when a reduced reference signal is available. The following are example applications that can use this Recommendation:

- 1) Interlaced video television streams over cable networks including those transmitted over the Internet using Internet Protocol.
- 2) Some forms of Internet Protocol Television (IPTV) video payloads.
- 3) Video quality monitoring at the receiver when side-channels are available.
- 4) Video quality monitoring at measurement nodes located between the point of transmission and the point of reception.

History

Edition	Recommendation	Approval	Study Group
1.0	ITU-T J.249	2010-01-13	9

FOREWORD

The International Telecommunication Union (ITU) is the United Nations specialized agency in the field of telecommunications, information and communication technologies (ICTs). The ITU Telecommunication Standardization Sector (ITU-T) is a permanent organ of ITU. ITU-T is responsible for studying technical, operating and tariff questions and issuing Recommendations on them with a view to standardizing telecommunications on a worldwide basis.

The World Telecommunication Standardization Assembly (WTSA), which meets every four years, establishes the topics for study by the ITU-T study groups which, in turn, produce Recommendations on these topics.

The approval of ITU-T Recommendations is covered by the procedure laid down in WTSA Resolution 1.

In some areas of information technology which fall within ITU-T's purview, the necessary standards are prepared on a collaborative basis with ISO and IEC.

NOTE

In this Recommendation, the expression "Administration" is used for conciseness to indicate both a telecommunication administration and a recognized operating agency.

Compliance with this Recommendation is voluntary. However, the Recommendation may contain certain mandatory provisions (to ensure e.g., interoperability or applicability) and compliance with the Recommendation is achieved when all of these mandatory provisions are met. The words "shall" or some other obligatory language such as "must" and the negative equivalents are used to express requirements. The use of such words does not suggest that compliance with the Recommendation is required of any party.

INTELLECTUAL PROPERTY RIGHTS

ITU draws attention to the possibility that the practice or implementation of this Recommendation may involve the use of a claimed Intellectual Property Right. ITU takes no position concerning the evidence, validity or applicability of claimed Intellectual Property Rights, whether asserted by ITU members or others outside of the Recommendation development process.

As of the date of approval of this Recommendation, ITU had received notice of intellectual property, protected by patents, which may be required to implement this Recommendation. However, implementers are cautioned that this may not represent the latest information and are therefore strongly urged to consult the TSB patent database at <http://www.itu.int/ITU-T/ipr/>.

Recommendation ITU-T J.249

Perceptual video quality measurement techniques for digital cable television in the presence of a reduced reference

1 Scope

This RRNR-TV (reduced reference and no reference objective models for standard definition television) test addresses two video formats (525-line and 625-line). Reduced reference (RR) models have limited bandwidth access to the source video. For an RR model to operate correctly, the unimpaired source video should be available for the models to extract parameters.

The hypothetical reference circuits (HRCs) in each experiment spanned both coding-only artefacts and coding with transmission errors. The coding schemes examined were MPEG-2 and ITU-T H.264 (MPEG-4 part 10). The MPEG-2 encoders were run at a variety of bit rates from 1.0 to 5.5 Mbit/s. The ITU-T H.264 encoders were run at a variety of bit rates ranging from 1.0 to 3.98 Mbit/s. Each experiment included 12 source sequences, of which two were secret source. Each experiment included 34 HRCs, and 156 processed video sequences (PVSs). Of these PVSs, 40 contained transmission errors and 116 contained coding only.

Although the models defined in this Recommendation may be used to compare video system performance (e.g., comparing two codecs), readers should be aware that the models contained in this Recommendation were not validated for such applications.

None of the evaluated models reached the accuracy of the normative subjective testing.

1.1 Applications

This Recommendation provides video quality estimations for video classes TV 3 to MM 5b, as defined in Annex B of [ITU-T P.911]. The applications for the estimation models described in this Recommendation include, but are not limited to:

- 1) potentially real-time, in-service quality monitoring at the source;
- 2) remote destination quality monitoring when side-channels are available for features extracted from source video sequences;
- 3) quality measurement for monitoring of a storage or transmission system that utilizes video compression and decompression techniques, either a single pass or a concatenation of such techniques;
- 4) lab testing of video systems.

1.2 Model usage

This Recommendation includes the objective computational models shown in Table 1.

Table 1 – Model description

Model index	Name	Country	Annex
Model_A	Yonsei University	Korea (Republic of)	A
Model_B	NEC	Japan	B
Model_C	National Telecommunications and Information Administration/Institute for Telecommunication Sciences (NTIA/ITS)	United States of America	C

For the 525-line format, all the six models (Model_A 15k, Model_A 80k, Model_A 256k, Model_C 80k, Model_B 80k, Model_B 256k) significantly outperform or are equivalent to peak signal-to-noise ratio (PSNR). These six models can be used for the 525-line format.

For the 625-line format, four models (Model_A 15k, Model_A 80k, Model_A 256k, Model_C 80k) significantly outperform PSNR. These four models can be used for the 625-line format.

Table 2 shows the recommended formats for which the models can be used. Table 3 shows the validated performance (reported as correlations) for each model.

Table 2 – Model usage

Side-channel bandwidth	525-line format	625-line format
15 kbit/s	Model_A	Model_A
80 kbit/s	Model_A, Model_C, Model_B	Model_A, Model_C
256 kbit/s	Model_A, Model_B	Model_A

Table 3 – Model performance overview (correlations)

	Model_A 15k	Model_A 80k	Model_A 256k	Model_B 80k	Model_B 256k	Model_C 80k	PSNR
525-line format	0.906	0.903	0.903	0.795	0.803	0.882	0.826
625-line format	0.894	0.899	0.898	NA	NA	0.866	0.857

1.3 Limitations

The estimation models described in this Recommendation cannot be used to fully replace subjective testing. Correlation values between two carefully designed and executed subjective tests (i.e., in two different laboratories) normally fall within the range 0.93 to 0.98. If this Recommendation is utilized to make video system comparisons (e.g., comparing two codecs), it is advisable to use a quantitative method (such as that in [b-ITU-T J.149]) to determine the models' accuracy for that particular context.

The models in this Recommendation were validated by measuring video that exhibits frame freezes of up to 2 seconds. The models were evaluated assuming that the first second and final second of each 8-second video sequence maintained temporal alignment (with ± 0.25 -second margin). Users of this Recommendation should make sure that there are no temporal alignment problems at the beginning or end of the processed video sequence (PVS).

The reduced reference information can not have any transmission impairments (i.e., the bottom feature extraction path shown in Figures 1 and 2).

The models in this Recommendation were not validated for measuring video that has a steadily increasing delay (e.g., video which does not discard missing frames after a frame freeze).

For detailed test conditions and calibration limits under which the models were validated, users are referred to the RRNR-TV test plan published by VQEG.

It should be noted that in case of new coding and transmission technologies producing artefacts which were not included in this evaluation, the objective models may produce erroneous results. Here, a subjective evaluation is required.

2 References

The following ITU-T Recommendations and other references contain provisions which, through reference in this text, constitute provisions of this Recommendation. At the time of publication, the editions indicated were valid. All Recommendations and other references are subject to revision; users of this Recommendation are therefore encouraged to investigate the possibility of applying the most recent edition of the Recommendations and other references listed below. A list of the currently valid ITU-T Recommendations is regularly published. 3 Definitions

3.1 Terms defined elsewhere

This Recommendation uses the following terms defined elsewhere:

3.1.1 objective perceptual measurement (picture) [ITU-T J.144]: The measurement of the performance of a programme chain by the use of programme-like pictures and objective (instrumental) measurement methods to obtain an indication that approximates the rating that would be obtained from a subjective assessment test.

3.1.2 proponent [ITU-T J.144]: An organization or company that proposes a video quality model for validation testing and possible inclusion in an ITU Recommendation.

3.1.3 subjective assessment (picture) [ITU-T J.144]: The determination of the quality or impairment of programme-like pictures presented to a panel of human assessors in viewing sessions.

3.2 Terms defined in this Recommendation

This Recommendation defines the following terms:

3.2.1 frame rate: The number of unique frames (i.e., total frames – repeated frames) per second.

3.2.2 simulated transmission errors: Errors imposed upon the digital video bit stream in a highly controlled environment. Examples include simulated packet loss rates and simulated bit errors. Parameters used to control simulated transmission errors are well defined.

3.2.3 transmission errors: Any error imposed on the video transmission. Example types of errors include simulated transmission errors and live network conditions.

4 Abbreviations and acronyms

This Recommendation uses the following abbreviations and acronyms:

ACR	Absolute Category Rating
ACR-HR	Absolute Category Rating with Hidden Reference
ATI	Absolute Temporal Information
AVI	Audio Video Interleave
DMOS	Difference Mean Opinion Score
EPSNR	Edge Peak Signal-to-Noise Ratio
FR	Full Reference
FRTV	Full Reference TeleVision
HRC	Hypothetical Reference Circuit
HV	Horizontal and Vertical
ILG	VQEG's Independent Laboratory Group
LPF	Low Pass Filter
MAD	Mean Absolute Difference
MB	Macro-Block
MM 5b	MultiMedia video class 5b
MOS	Mean Opinion Score
MOSp	Mean Opinion Score, predicted
MPEG	Moving Picture Experts Group
NFD	Normalized Frame Difference
NHFE	Normalized High Frequency Energy
NR	No (or zero) Reference
OR	Outlier Ratio
PSNR	Peak Signal-to-Noise Ratio
PVS	Processed Video Sequence
RMSE	Root Mean Square Error
RR	Reduced Reference
RRNR-TV	Reduced Reference and No Reference objective models for standard definition TeleVision
SFR	Source Frame Rate
SI	Spatial Information
SNFD	Source Normalized Frame Difference
SNMPE	Source Normalized High Frequency Energy
SRC	Source Reference Channel or Circuit
TV 3	TeleVision class 3
VQEG	Video Quality Experts Group

5 Conventions

None.

6 Description of the reduced reference measurement method

The double-ended measurement method with reduced reference, for objective measurement of perceptual video quality, evaluates the performance of systems by making a comparison between features extracted from the undistorted input, or reference, video signal at the input of the system, and the degraded signal at the output of the system (Figure 1).

Figure 1 shows an example of application of the reduced reference method to test a codec in the laboratory.

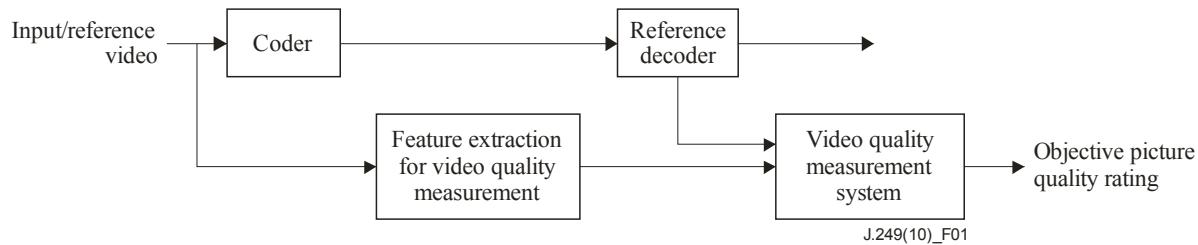

Figure 1 – Application of the reduced reference perceptual quality measurement method to test a codec in the laboratory

The comparison between input and output signals may require a temporal alignment or a spatial alignment process, the latter to compensate for any vertical or horizontal picture shifts or cropping. It also may require correction for any offsets or gain differences in both the luminance and the chrominance channels. The objective picture quality rating is then calculated, typically by applying a perceptual model of human vision.

Alignment and gain adjustment is known as normalization. This process is required because most reduced reference methods compare the features extracted from reference pictures and processed pictures on what is effectively a pixel-by-pixel basis. An example would be calculation of peak signal-to-noise ratio (PSNR). Only time-invariant static changes in the video are removed, dynamic changes due to the system under test are measured as part of the quality rating calculation. [ITU-T J.244] and [ITU-T J.144] provide standard methods for reporting values needed for normalizing video prior to objective quality assessment. The video quality metrics described in Annexes A to C of this Recommendation include associated normalization methods. Alternate normalization methods can be used for the video quality metrics of Annexes A to C, provided they deliver the required normalization accuracy.

As the video quality metrics are typically based on approximations to human visual responses, rather than on the measurement of specific coding artefacts, they are in principle equally valid for analogue systems and for digital systems. They are also in principle valid for chains where analogue and digital systems are mixed, or where digital compression systems are concatenated.

Figure 2 shows an example of the application of the reduced reference method to test a transmission chain.

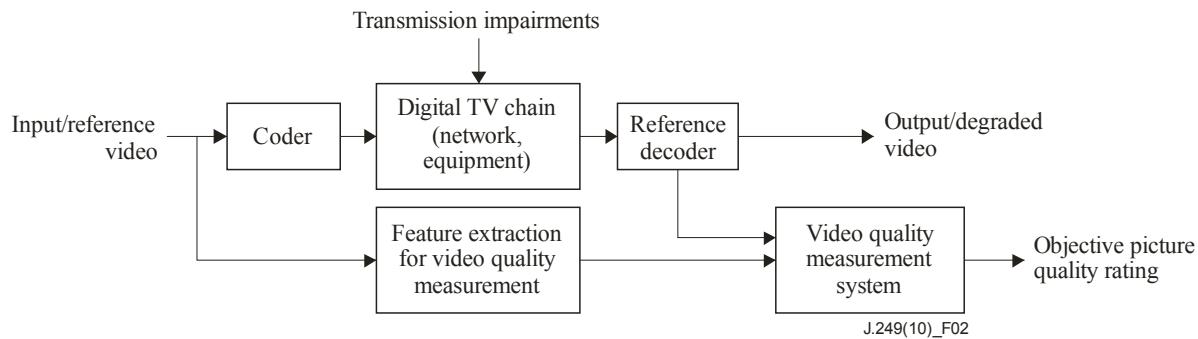

Figure 2 – Application of the reduced reference perceptual quality measurement method to test a transmission chain

In this case, a reference decoder is fed from various points in the transmission chain, e.g., the decoder can be located at a point in the network, as in Figure 2, or directly at the output of the encoder, as in Figure 1. If the digital transmission chain is transparent, the measurement of objective picture quality rating at the source is equal to the measurement at any subsequent point in the chain.

It is generally accepted that the full reference method provides the best accuracy for perceptual picture quality measurements. The method has been proven to have the potential for high correlation with subjective assessments made in conformity with the ACR-HR methods specified in [ITU-T P.910].

7 Findings of the Video Quality Experts Group (VQEG)

Studies of perceptual video quality measurements are conducted in an informal group, called the Video Quality Experts Group (VQEG), which reports to ITU-T Study Groups 9 and 12 and ITU-R Study Group 6. The recently completed RRNR-TV test of VQEG assessed the performance of proposed reduced reference perceptual video quality measurement algorithms for 525-line and 625-line formats.

Based on the present evidence, six RR methods (Model_A 15k, Model_A 80k, Model_A 256k, Model_C 80k, Model_B 80k (525-line only), Model_B 256k (525-line only) can be recommended by ITU-T at this time.

The technical descriptions of these models can be found in Annexes A through C, respectively. Note that the ordering of annexes is purely arbitrary and provides no indication of quality prediction performance.

Tables 4 and 5 show significance tests in the VQEG RRNR-TV test. For the 525-line format, four models (Model_A 15k, Model_A 80k, Model_A 256k, Model_C 80k) are statistically better than PSNR and two models (Model_B 80k, Model_B 256k) are statistically equivalent to PSNR. It should be noted that PSNR was computed by NTIA using an exhaustive search of calibration limits. For the 625-line format, four models (Model_A 15k, Model_A 80k, Model_A 256k, Model_C 80k) are statistically equivalent, and are statistically better than PSNR.

Table 4 – Significance test for the 525-line format

525-line format	Compare best	Compare PSNR	Correlation
Model_A 15k	1	1	0.906
Model_A 80k	1	1	0.903
Model_A 256k	1	1	0.903
Model_C 80k	1	1	0.882
Model_B 80k	0	1	0.795
Model_B 256k	0	1	0.803
PSNR_NTIA	0	1	0.826

NOTE – "1" in "compare best" indicates that this model is statistically equivalent to the top performing model; "0" indicates that this model is not statistically equivalent to the top performing model. "1" in "compare PSNR" indicates that this model is statistically equivalent to the top performing model; "0" indicates that this model is not statistically equivalent to the top performing model.

Table 5 – Significance test for the 625-line format

625-line format	Compare best	Compare PSNR	Correlation
Model_A 15k	1	1	0.894
Model_A 80k	1	1	0.899
Model_A 256k	1	1	0.898
Model_C 80k	1	1	0.866
PSNR_NTIA	0	1	0.857

NOTE – "1" in "compare best" indicates that this model is statistically equivalent to the top performing model; "0" indicates that this model is not statistically equivalent to the top performing model. "1" in "compare PSNR" indicates that this model is statistically equivalent to the top performing model; "0" indicates that this model is not statistically equivalent to the top performing model.

Tables 6 and 7 below provide informative details on the models' performances in the VQEG RRNR-TV test.

Table 6 – Informative description on the models' performance in the VQEG RRNR-TV test (525-line format)

525-line format	Correlation	RMSE	OR
Model_A 15k	0.906	0.418	0.385
Model_A 80k	0.903	0.423	0.378
Model_A 256k	0.903	0.424	0.378
Model_B 80k	0.795	0.598	0.667
Model_B 256k	0.803	0.587	0.647
Model_C 80k	0.882	0.465	0.513
PSNR_NTIA	0.826	0.556	0.571

Table 7 – Informative description on the models' performance in the VQEG RRNR-TV test (625-line format)

625-line format	Correlation	RMSE	OR
Model_A 15k	0.894	0.524	0.468
Model_A 80k	0.899	0.513	0.462
Model_A 256k	0.898	0.516	0.468

PSNR_NTIA	0.857	0.605	0.564

Annex A

Model_A: Yonsei University, HDSP Laboratory (15 kbit/s model, 80 kbit/s model, 256 kbit/s model)

(This annex forms an integral part of this Recommendation)

A.1 Introduction

Although PSNR has been widely used as an objective video quality measure, it is also reported that it does not well represent perceptual video quality. By analyzing how humans perceive video quality, it is observed that the human visual system is sensitive to degradation around the edges. In other words, when the edge pixels of a video are blurred, evaluators tend to give low scores to the video even though the PSNR is high. Based on this observation, the reduced reference models which mainly measure edge degradations have been developed.

Figure A.1 illustrates how a reduced reference model works. Features which will be used to measure video quality at a monitoring point are extracted from the source video sequence and transmitted. Table A.1 shows the side-channel bandwidths for the features, which have been tested in the VQEG RRNR-TV test.

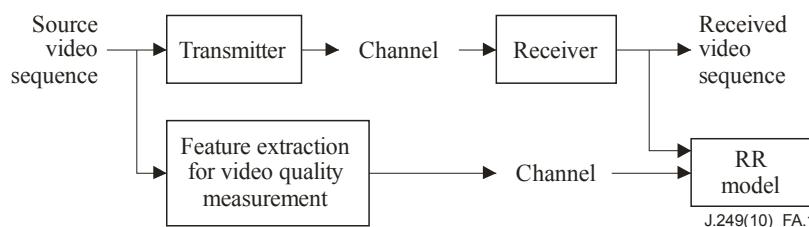

Figure A.1 – Block diagram of reduced reference model

Table A.1 – Side-channel bandwidths

Video format	Tested bandwidths
525-line format	15 kbit/s, 80 kbit/s, 256 kbit/s
625-line format	15 kbit/s, 80 kbit/s, 256 kbit/s

A.2 The EPSNR reduced reference models

A.2.1 Edge peak signal-to-noise ratio (EPSNR)

The RR models mainly measure edge degradations. In the models, an edge detection algorithm is first applied to the source video sequence to locate the edge pixels. Then, the degradation of those edge pixels is measured by computing the mean squared error. From this mean squared error, the edge PSNR is computed.

One can use any edge detection algorithm, though there may be minor differences in the results. For example, one can use any gradient operator to locate edge pixels. A number of gradient operators have been proposed. In many edge detection algorithms, the horizontal gradient image $g_{horizontal}(m,n)$ and the vertical gradient image $g_{vertical}(m,n)$ are first computed using gradient operators. Then, the magnitude gradient image $g(m,n)$ may be computed as described below.

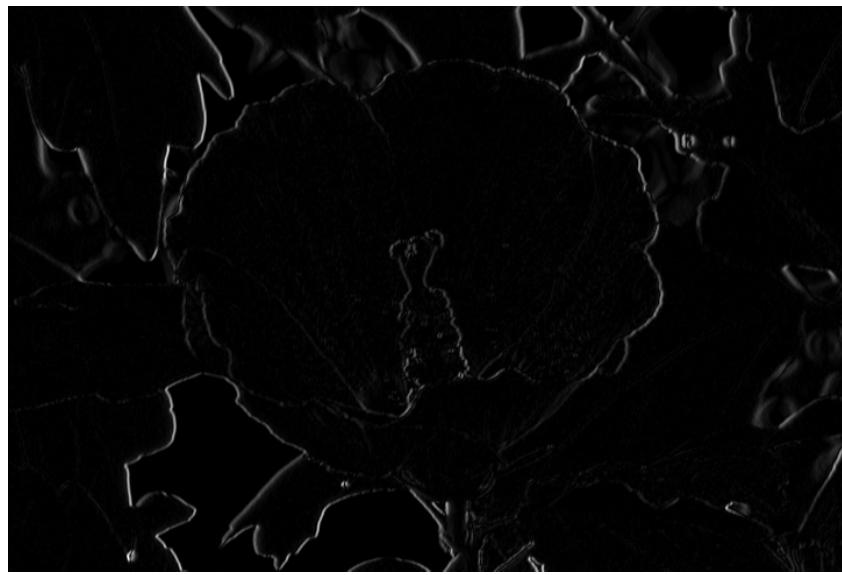

Finally, a thresholding operation is applied to the magnitude gradient image to find edge pixels. In other words, pixels whose magnitude gradients exceed a threshold value are considered to be edge pixels.

Figures A.2 to A.6 illustrate the procedure. Figure A.2 shows a source image. Figure A.3 shows a horizontal gradient image $g_{horizontal}(m,n)$, which is obtained by applying a horizontal gradient operator to the source image of Figure A.2. Figure A.4 shows a vertical gradient image $g_{vertical}(m,n)$, which is obtained by applying a vertical gradient operator to the source image of Figure A.2. Figure A.5 shows the magnitude gradient image (edge image) and Figure A.6 shows the binary edge image (mask image) obtained by applying thresholding to the magnitude gradient image of Figure A.5.

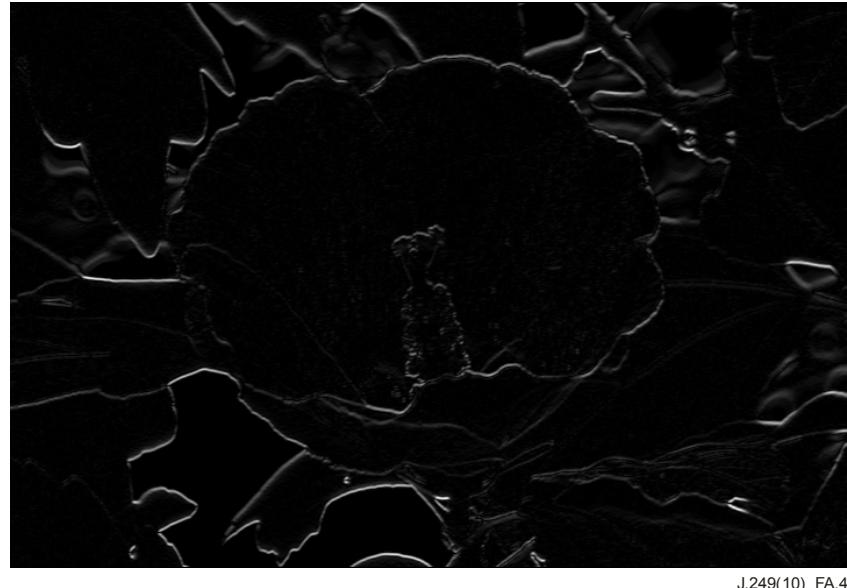

J.249(10)_FA.2

Figure A.2 – Source image (original image)

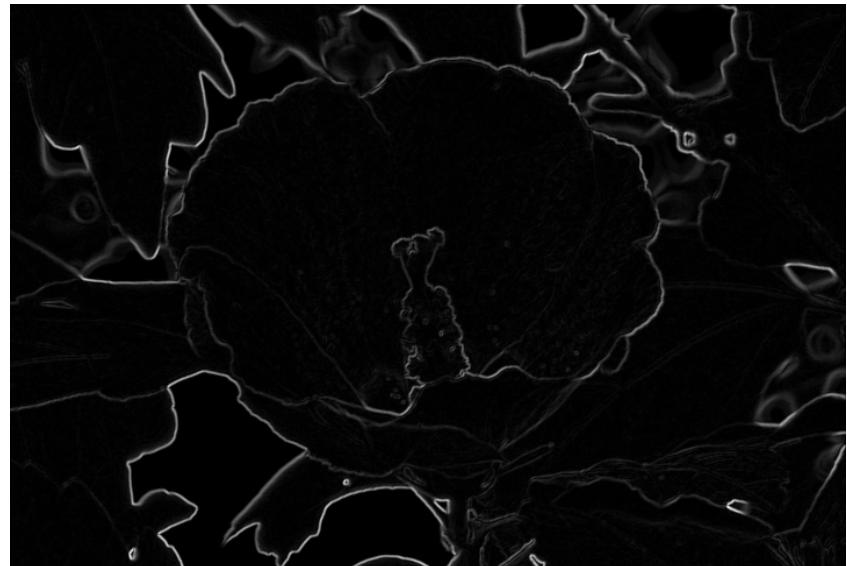

J.249(10)_FA.3

Figure A.3 – Horizontal gradient image, which is obtained by applying a horizontal gradient operator to the source image of Figure A.2

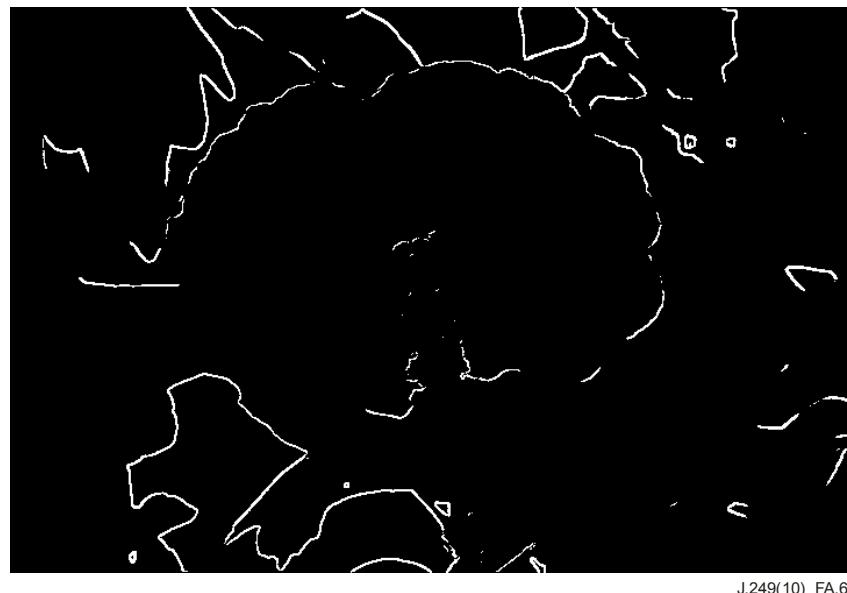

J.249(10)_FA.4

Figure A.4 – Vertical gradient image, which is obtained by applying a vertical gradient operator to the source image of Figure A.2

J.249(10)_FA.5

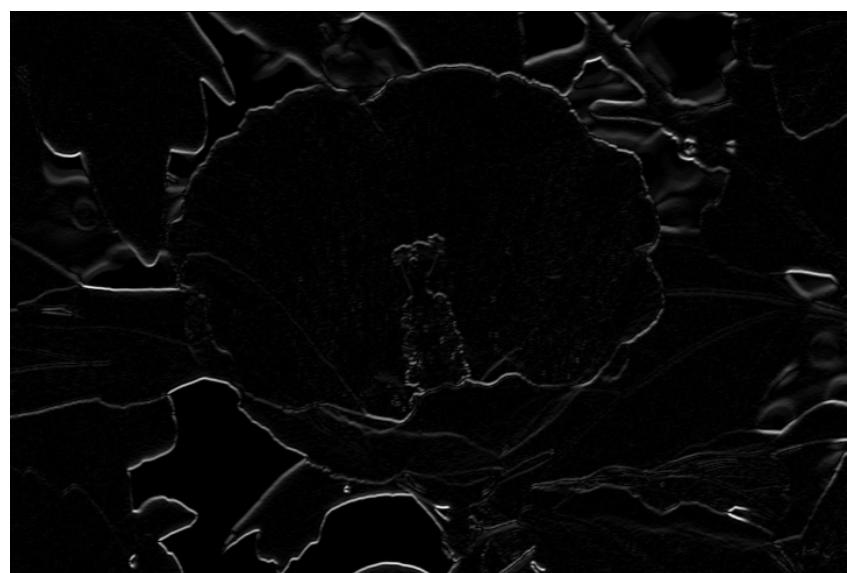

Figure A.5 – Magnitude gradient image

J.249(10)_FA.6

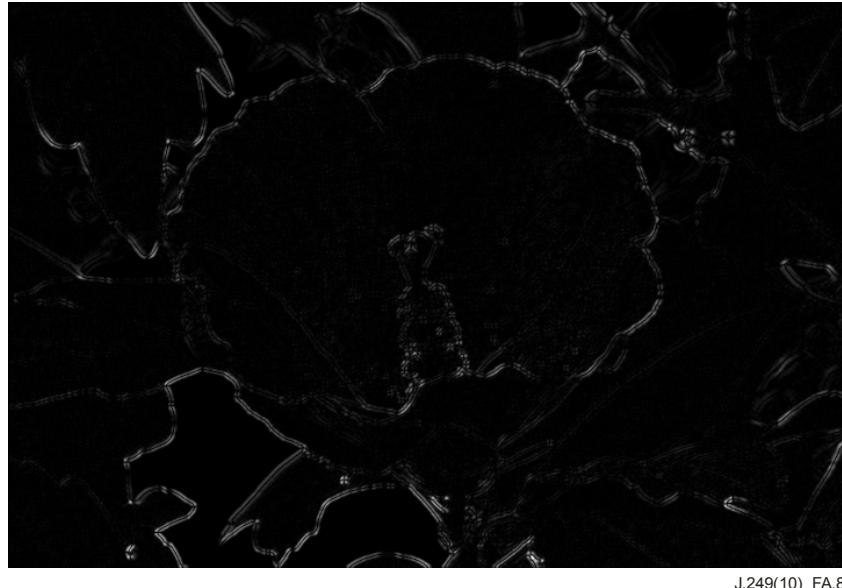

Figure A.6 – Binary edge image (mask image) obtained by applying thresholding to the magnitude gradient image of Figure A.5

Alternatively, one may use a modified procedure to find edge pixels. For instance, one may first apply a vertical gradient operator to the source image, producing a vertical gradient image. Then, a horizontal gradient operator is applied to the vertical gradient image, producing a modified successive gradient image (horizontal and vertical gradient image). Finally, a thresholding operation may be applied to the modified successive gradient image to find edge pixels. In other words, pixels of the modified successive gradient image, which exceed a threshold value, are considered as edge pixels. Figures A.7 to A.10 illustrate the modified procedure. Figure A.7 shows a vertical gradient image $g_{vertical}(m,n)$, which is obtained by applying a vertical gradient operator to the source image of Figure A.2. Figure A.8 shows a modified successive gradient image (horizontal and vertical gradient image), which is obtained by applying a horizontal gradient operator to the vertical gradient image of Figure A.7. Figure A.9 shows the binary edge image (mask image) obtained by applying thresholding to the modified successive gradient image of Figure A.8.

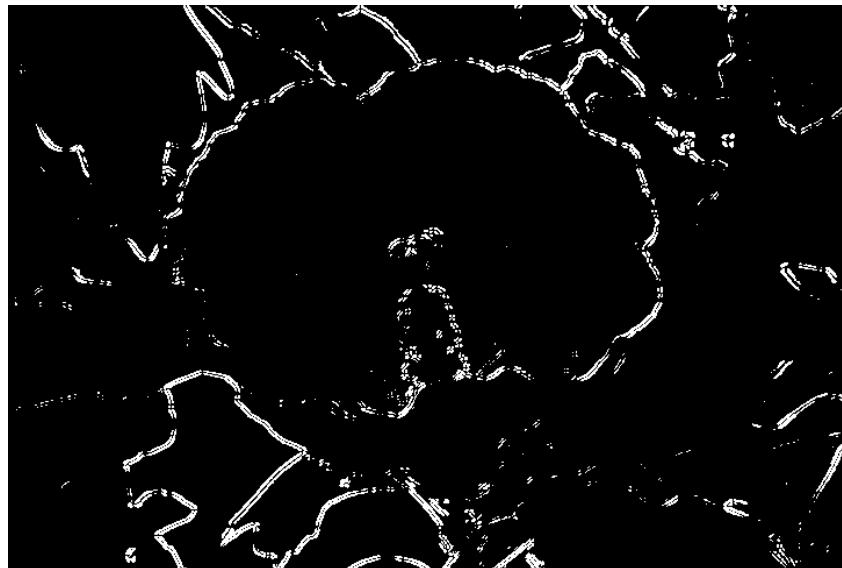

J.249(10)_FA.7

Figure A.7 – Vertical gradient image, which is obtained by applying a vertical gradient operator to the source image of Figure A.2

J.249(10)_FA.8

Figure A.8 – Modified successive gradient image (horizontal and vertical gradient image), which is obtained by applying a horizontal gradient operator to the vertical gradient image of Figure A.7

J.249(10)_FA.9

Figure A.9 – Binary edge image (mask image) obtained by applying thresholding to the modified successive gradient image of Figure A.8

It is noted that both methods can be understood as an edge detection algorithm. One may choose any edge detection algorithm depending on the nature of videos and compression algorithms. However, some methods may outperform other methods.

Thus, in the model, an edge detection operator is first applied, producing edge images (Figures A.5 and A.8). Then, a mask image (binary edge image) is produced by applying thresholding to the edge image (Figures A.6 and A.9). In other words, pixels of the edge image whose value is smaller than threshold t_e are set to zero, and pixels whose value is equal to or larger than the threshold are set to a non-zero value. Figures A.6 and A.9 show some mask images. Since a video can be viewed as a sequence of frames or fields, the above-stated procedure can be applied to each frame or field of videos. Since the model can be used for field-based videos or frame-based videos, the terminology "image" will be used to indicate a field or frame.

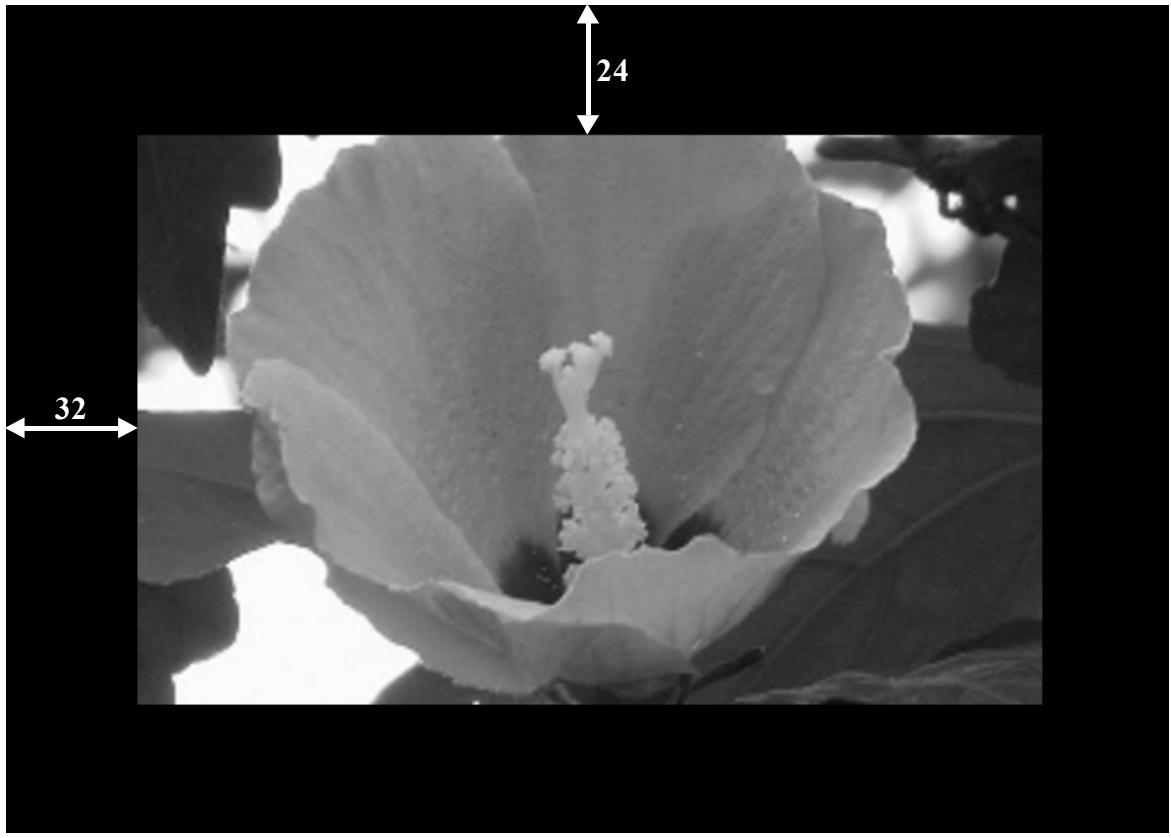

A.2.2 Selecting features from source video sequences

Since the model is a reduced reference (RR) model, a set of features need to be extracted from each image of a source video sequence. In the EPSNR RR model, a certain number of edge pixels are selected from each image. Then, the locations and pixel values are encoded and transmitted. However, for some video sequences, the number of edge pixels can be very small when a fixed threshold value is used. In the worst scenario, it can be zero (blank images or very low frequency images). In order to address this problem, if the number of edge pixels of an image is smaller than a given value, the user may reduce the threshold value until the number of edge pixels is larger than a given value. Alternatively, one can select edge pixels which correspond to the largest values of the horizontal and vertical gradient image. When there are no edge pixels (e.g., blank images) in a frame, one can randomly select the required number of pixels or skip the frame. For instance, if ten edge pixels are to be selected from each frame, one can sort the pixels of the horizontal and vertical gradient image according to their values and select the largest ten values. However, this procedure may produce multiple edge pixels at identical locations. To address this problem, one can first select several times the desired number of pixels of the horizontal and vertical gradient image and then randomly choose the desired number of edge pixels among the selected pixels of the horizontal and vertical gradient image. In the models tested in the VQEG RRNR-TV test, the desired number of edge pixels is randomly selected among a large pool of edge pixels. The pool of edge pixels is obtained by applying a thresholding operation to the gradient image.

In the EPSNR RR models, the locations and edge pixel values are encoded after a Gaussian low pass filter (LPF) is applied to the selected pixel locations. Although the Gaussian LPF (5 x 3) was used in the VQEG RRNR-TV test, different low pass filters may be used depending on video formats. It is noted that during the encoding process, cropping may be applied. In order to avoid selecting edge pixels in the cropped areas, the model selects edge pixels in the middle area (Figure A.10). Table A.2 shows the sizes after cropping. Table A.2 also shows the number of bits required to encode the location and pixel value of an edge pixel.

Table A.2 – Bits requirement per edge pixel

Video format	Size	Size after cropping	Bits for location	Bits for pixel value	Total bits per pixel
525-line format	720 x 486	656 x 438	19	8	27
625-line format	720 x 576	656 x 528	19	8	27

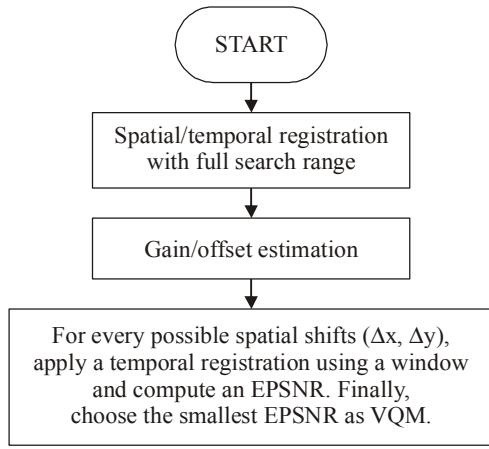

J.249(10)_FA.10

Figure A.10 – An example of cropping and the middle area

The model selects edge pixels from each frame in accordance with the allowed bandwidth (Table A.1). Table A.3 shows the number of edge pixels per frame which can be transmitted for the tested bandwidths.

Table A.3 – Number of edge pixels per frame

Video format	15 kbit/s	80 kbit/s	256 kbit/s
525-line format	16	74	238
625-line format	20	92	286

J.249(10)_FA.11

Figure A.11 – Flowchart of the model

A.2.3 Spatial/temporal registration and gain/offset adjustment

Before computing the difference between the edge pixels of the source video sequence and those of the processed video sequence, which is the received video sequence at the receiver, the model first applies a spatial/temporal registration and gain/offset adjustment. The calibration method described in Annex B of [ITU-T J.244] was used. To transmit the gain and offset features of Annex B of [ITU-T J.244], 30% of available bandwidth was used in the VQEG RRNR-TV test. Since the video sequence is interlaced, the calibration method is applied three times: the even fields, odd fields and combined frames. If the difference between the even field error (PSNR) and the odd field error is greater than a threshold, the registration results (x-shift, y-shift) with the smaller PSNR were used. Otherwise, the registration results with the combined frames were used. In the VQEG RRNR-TV test, the threshold was set to 2 dB.

At the monitoring point, the processed video sequence should be aligned with the edge pixels extracted from the source video sequence. However, if the side-channel bandwidth is small, only a few edge pixels of the source video sequence are available (Figure A.12). Consequently, the temporal registration can be inaccurate if the temporal registration is performed using a single frame (Figure A.13). To address this problem, the model uses a window for temporal registration. Instead of using a single frame of the processed video sequence, the model builds a window which consists of a number of adjacent frames to find the optimal temporal shift. Figure A.14 illustrates the procedure. The mean squared error within the window is computed as follows:

$$MSE_{window} = \frac{1}{N_{win}} \sum (E_{SRC}(i) - E_{PVS}(i))^2$$

where MSE_{window} is the window mean squared error, $E_{SRC}(i)$ is an edge pixel within the window which has a corresponding pixel in the processed video sequence, $E_{PVS}(i)$ is a pixel of the processed video sequence corresponding to the edge pixel, and N_{win} is the total number of edge pixels used to compute MSE_{window} . This window mean squared error is used as the difference between a frame of the processed video sequence and the corresponding frame of the source video sequence.

The window size can be determined by considering the nature of the processed video sequence. For a typical application, a window corresponding two seconds is recommended. Alternatively, various sizes of windows can be applied and the best one which provides the smallest mean squared error can be used. Furthermore, different window centres can be used to consider frame skipping due to transmission errors (Figure A.18).

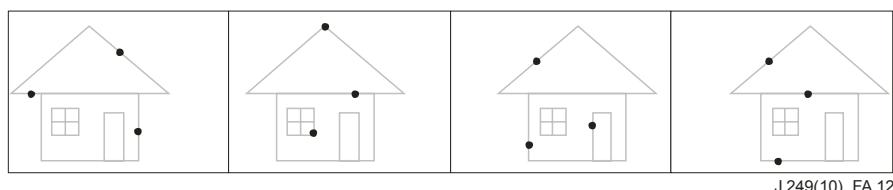

Figure A.12 – Edge pixel selection of the source video sequence

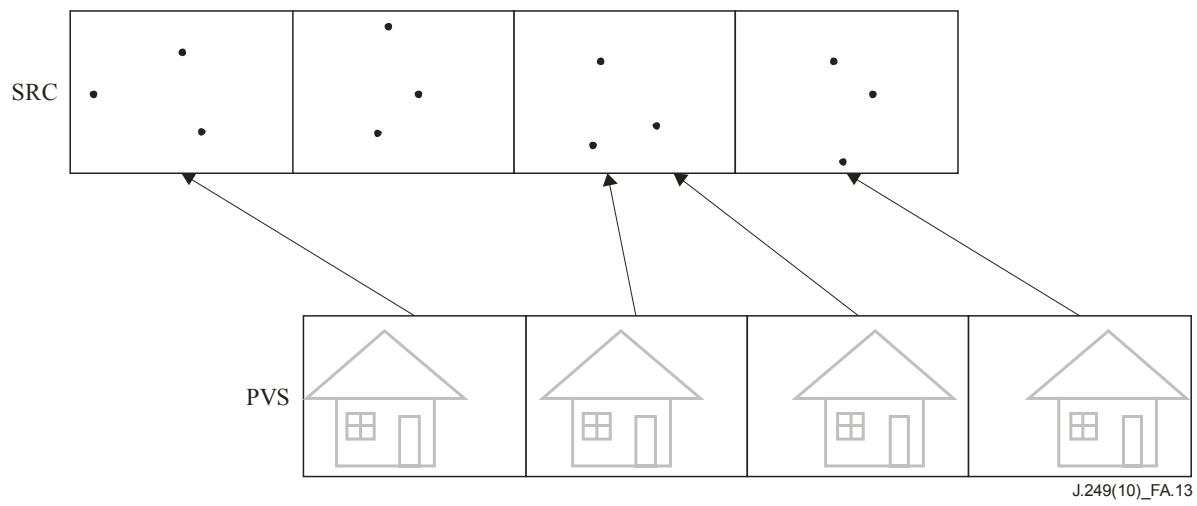

Figure A.13 – Aligning the processed video sequence to the edge pixels of the source video sequence

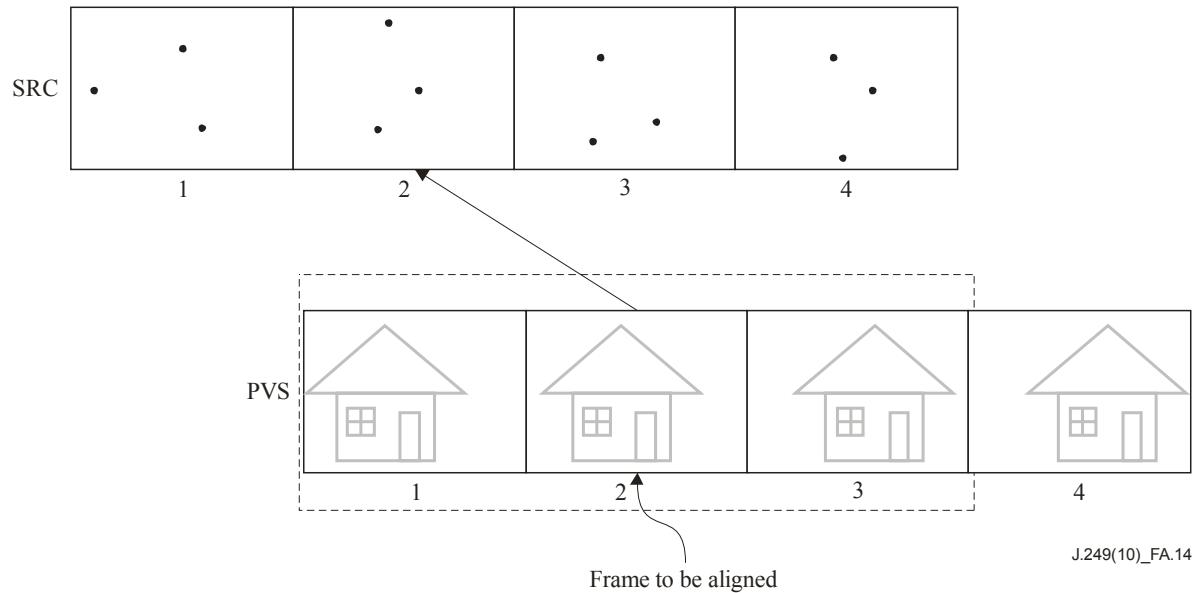

Figure A.14 – Aligning the processed video sequence to the edge pixels using a window

When the source video sequence is encoded at high compression ratios, the encoder may reduce the number of frames per second and the processed video sequence has repeated frames (Figure A.15). In Figure A.15, the processed video sequence does not have frames corresponding to some frames of the source video sequence (frames 2, 4, 6, 8). In this case, the model does not use repeated frames in computing the mean squared error. In other words, the model performs temporal registration using the first frame (valid frame) of each repeated block. Thus, in Figure A.16, only three frames (frames 3, 5, 7) within the window are used for temporal registration.

SRC	A	B	C	D	E	F	G	H
	1	2	3	4	5	6	7	8
PVS	A	A	C	C	E	E	G	G
	1	2	3	4	5	6	7	8

J.249(10)_FA.15

Figure A.15 – Example of repeated frames

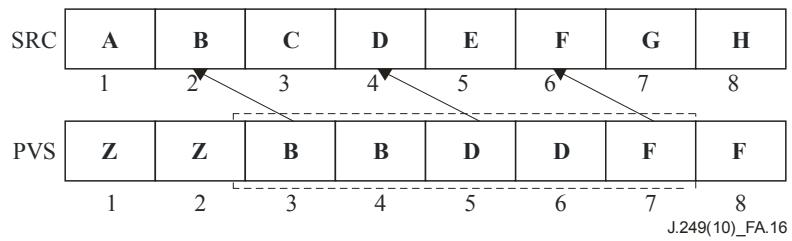

Figure A.16 – Handling repeated frames

It is possible to have a processed video sequence with irregular frame repetition, which may cause the temporal registration method using a window to produce inaccurate results. To address this problem, it is possible to locally adjust each frame of the window within a given value (e.g., ± 1), as shown in Figure A.19, after the temporal registration using a window. Then, the local adjustment which provides the minimum MSE is used to compute the EPSNR.

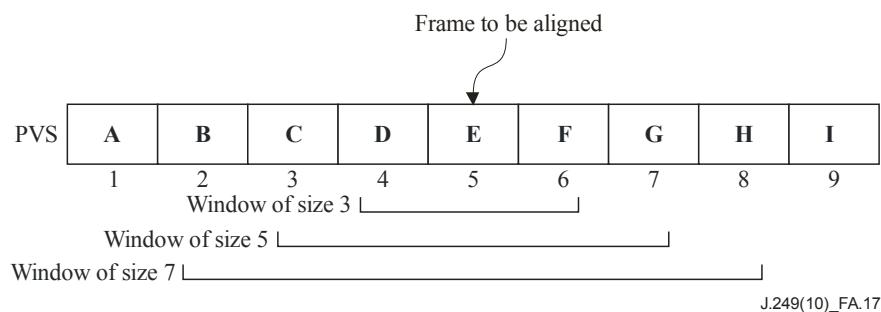

Figure A.17 – Windows of various sizes

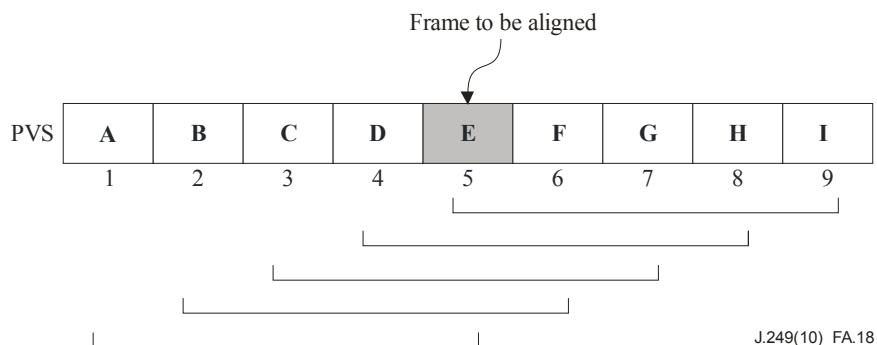

Figure A.18 – Window centres

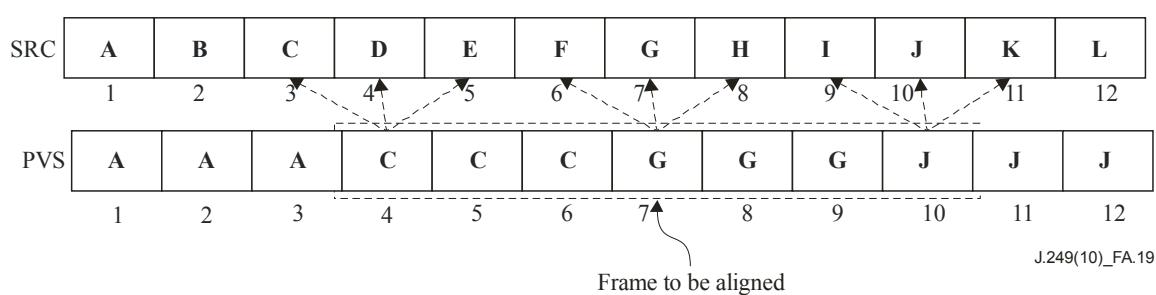

Figure A.19 – Local adjustment for temporal registration using a window

A.2.4 Computing EPSNR and post-processing

After temporal registration is performed, the average of the differences between the edge pixels of the source video sequence and the corresponding pixels of the processed video sequence is computed, which can be understood as the edge mean squared error of the processed video sequence (MSE_{edge}). Finally, the EPSNR (edge PSNR) is computed as follows:

$$EPSNR = 10 \log_{10} \left(\frac{P^2}{MSE_{edge}} \right)$$

where P is the peak value of the image.

- 1) Freezed frames.

There can be frame repeating due to reduced frame rates and frame freezing due to transmission error, which will degrade perceptual video quality. In order to address this effect, the model applies the following adjustment before computing the EPSNR:

$$MSE_{freezed_frame_considered} = MSE_{edge} \times \frac{K \times N_{total_frame}}{N_{total_frame} - N_{total_freezed_frame}}$$

where $MSE_{freezed_frame_considered}$ is the mean squared error which takes into account repeated and freezed frames, N_{total_frame} is the total number of frames, $N_{total_freezed_frame}$, K is constant. In the model tested in the VQEG RRNR-TV test, K was set to 1.

- 2) High frequency and fast motions.

If the video sequence contains a large amount of high frequencies and fast motions, the perceptual quality tends to increase for the same MSE. To consider this effect, the normalized frame difference (NFD) and the normalized high frequency energy (NHFE) are defined as follows:

$$NFD = \frac{FD}{\text{average energy per pixel}}$$

where $FD = \frac{1}{N_F} \sum_i \sum_{k=1}^{height} \sum_{j=1}^{width} (Frame_i[j,k] - Frame_{i-1}[j,k])^2$ and N_F is the number of frames used in the summation.

It is noted that the largest three frame differences are excluded in computing FD in order to exclude scene changes in computing the average frame difference, assuming 8-second video sequences. The normalized high frequency energy (NHFE) is calculated by computing the average high frequency energies (Figure A.20) after the 2D Fourier transform is applied:

$$NHFE = \frac{\text{average high frequency energies}}{\text{average energy per pixel}}$$

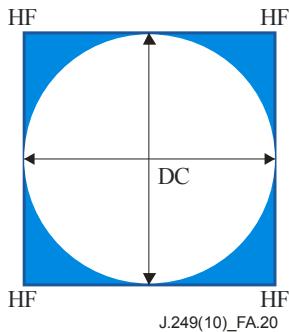

Finally, the following equations are used:

```

IF(SNFD > 0.35 && SNHFE > 2.5) {
    IF(EPSNR < 20) EPSNR = EPSNR+3
    ELSE IF(EPSNR < 35) EPSNR = EPSNR+5
}
ELSE IF((SNFD > 0.2 && SNHFE > 1.5) || (SNFD>0.27) && SNHFE > 1.3)) {
    IF(28 < EPSNR < 40) EPSNR = EPSNR + 3
    IF(EPSNR > 40) EPSNR = 40
}

```

where SNFD is the source NFD and SNHFE is the source NHFE. It is noted that SNFD and SNHFE are computed from SRC and transmitted as a part of feature data (1 byte for each).

NOTE – The high frequency energies are computed from the shaded area.

Figure A.20 – Computing the normalized high frequency energy (NHFE)

3) Blurring.

To consider blurring effects, the following equations are used:

```

IF (NHFE/SNHFE < 0.5)
    IF (EPSNR>26)    EPSNR = 26
ELSE IF (NHFE/SNHFE < 0.6)
    IF (EPSNR>32)    EPSNR = 32
ELSE IF (NHFE/SNHFE < 0.7)
    IF (EPSNR>36)    EPSNR = 36
ELSE IF (NHFE/SNHFE > 1.2)
    IF (EPSNR>23)    EPSNR = 23
ELSE IF (NHFE/SNHFE > 1.1)
    IF (EPSNR>25)    EPSNR = 25

```

where NHFE is the PVS NHFE.

4) Blocking.

To consider blocking effects, average column differences are computed. Assuming 8 modulo, the blocking score for the i -th frame is computed as follows:

$$Blk[i] = \frac{\text{largest column difference}}{\text{second largest column difference}}$$

The final blocking score (*Blocking*) is computed by averaging the frame blocking scores:

$$Blocking = \frac{1}{\text{number of frames}} \sum_i Blk[i]$$

Finally, the following equations are used:

```

IF (BLOCKING > 1.4) {
    IF (20≤EPSNR<25) EPSNR = EPSNR-1.086094*BLOCKING-0.601316
    ELSE IF (EPSNR<30) EPSNR = EPSNR-0.577891*BLOCKING-3.158586
    ELSE IF (EPSNR<35) EPSNR = EPSNR-0.223573*BLOCKING-3.125441
}

```

5) Maximum freezed frames.

Transmission errors may cause long freezed frames. To consider long freezed frames, the following equations are used:

```

IF (MAX_FREEZE > 22 AND EPSNR>28) EPSNR = 28
ELSE IF (MAX_FREEZE > 10 AND EPSNR>34) EPSNR = 34

```

where MAX_FREEZE is the largest duration of freezed frames. It is noted that if the video sequence is not 8 seconds, different thresholds should be used.

6) Piecewise linear fitting.

When the EPSNR exceeds a certain value, the perceptual quality becomes saturated. In this case, it is possible to set the upper bound of the EPSNR. Furthermore, when a linear relationship between the EPSNR and difference mean opinion score (DMOS) is desirable, one can apply a piecewise linear function as illustrated in Figure A.21. In the model tested in the VQEG RRNR-TV test, the upper bound is set to 48 and the lower bound is set to 15.

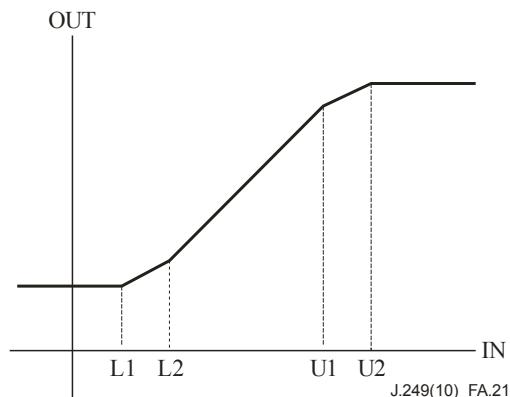

Figure A.21 – Piecewise linear function for linear relationship between the EPSNR and DMOS

A.3 Conclusions

The EPSNR reduced reference models for objective measurement of video quality are based on edge degradation. The models can be implemented in real time with moderate use of computing power. The models are well suited to applications which require real-time video quality monitoring where side-channels are available.

Annex B

Model_B: NEC (80 kbit/s, 256 kbit/s) [525-line format only]

(This annex forms an integral part of this Recommendation)

B.1 Summary

In the NEC reduced reference (RR) model, the activity values instead of the pixel values for individual given-size pixel blocks are transmitted to the client side. Video quality is estimated on the basis of the activity-difference between the source reference channel (SRC) and the processed video sequence (PVS). Psychovisual weightings with respect to the activity-difference are to improve estimation accuracy.

This model does not need computationally demanding spatial and gain-and-offset registrations. Moreover, it can be implemented by 30-line and 250-line programs on the server and the client sides, respectively. Therefore, it is suitable for real-time video quality monitoring in IPTV services that most benefits from low-complexity and easy implementation.

B.2 Definitions

Activity – An average of the absolute difference between each luminance value and the average of the luminance values for a given-size block.

Block – An MxN (M-column by N-row) array of pixels.

Frame – One complete television picture.

Gain – A multiplicative scaling factor applied by the hypothetical reference circuit (HRC) to all pixels of an individual image plane (e.g., luminance, chrominance). The gain of the luminance signal is commonly known as the contrast.

Hypothetical reference circuit (HRC) – A video system under test, such as a codec or digital video transmission system.

Luminance (Y) – The portion of the video signal that predominantly carries the luminance information (i.e., the black and white part of the picture).

National Television Systems Committee (NTSC) – The 525-line analogue colour video composite system [b-SMPTE 170M].

Offset (or level offset) – An additive factor applied by the hypothetical reference circuit (HRC) to all pixels of an individual image plane (e.g., luminance, chrominance). The offset of the luminance signal is commonly known as brightness.

Peak signal-to-noise ratio (PSNR) – A ratio between the maximum possible power of a signal and the power of corrupting noise.

Phase-altering line (PAL) – The 625-line analogue colour video composite system.

Raster scan – A mapping of a rectangular two-dimensional pattern to a one-dimensional pattern such that the first entry in the one-dimensional pattern is from the first top row of the two-dimensional pattern scanned from left to right, followed similarly by the second, third, etc., rows of the pattern (going down) each scanned from left to right.

Reduced reference (RR) – A video quality measurement methodology that utilizes low bandwidth features extracted from the original or processed video streams, as opposed to using full reference video that requires complete knowledge of the original and processed video streams. Reduced reference methodologies have advantages for end-to-end in-service quality monitoring since the reduced reference information is easily transmitted over ubiquitous telecommunication networks.

Region of interest (ROI) – An image lattice (specified in rectangle coordinates) that is used to denote a particular sub-region of a field or frame of video.

Scene – A sequence of video frames.

Spatial registration – A process that is used to estimate and correct spatial shifts of the processed video sequence with respect to the original video sequence.

Temporal registration – A process that is used to estimate and correct a temporal shift (i.e., video delay) of the processed video sequence with respect to the original video sequence.

Video quality metric (VQM) – An overall measure of video impairment. VQM is reported as a single number and has a nominal output range from zero to one, where zero is no perceived impairment and one is maximum perceived impairment.

B.3 Overview of the video quality metric (VQM) computation

The NEC RR model transmits the activity values for individual given-size pixel blocks to the client side. This value indicates the variance of the luminance values in the block. Figure B.1 summarizes the NEC RR model. As shown in Figure B.1, video quality is estimated on the basis of the activity-difference between the SRC and the PVS. In addition, psychovisual weightings with respect to the activity-difference are applied for higher estimation accuracy. Video quality estimation is conducted in the following steps:

- 1) The activity value for each 16x16 luminance pixel block of the SRC is calculated on the server side. All the activity values are then transmitted to the client side. The activity value of a block is defined as the mean absolute difference of individual values and their average.
- 2) The corresponding activity values are calculated on the client side with respect to the PVS.
- 3) On the client side, each block is initially evaluated with its squared error, that is the squared difference between the SRC and the PVS activity values.
- 4) Psychovisual weightings are applied to the squared errors in blocks with high spatial frequency components, a specific colour, a large inter-frame difference and a scene change.
- 5) A provisional video quality score is derived from the sum of the weighted squared errors in the same manner as in the PSNR calculation.
- 6) The score is modified to reflect perceptually fatal degradations due to blockiness and local impairment. Finally, the modified score represents the measured video quality of the PVS in the NEC RR model.

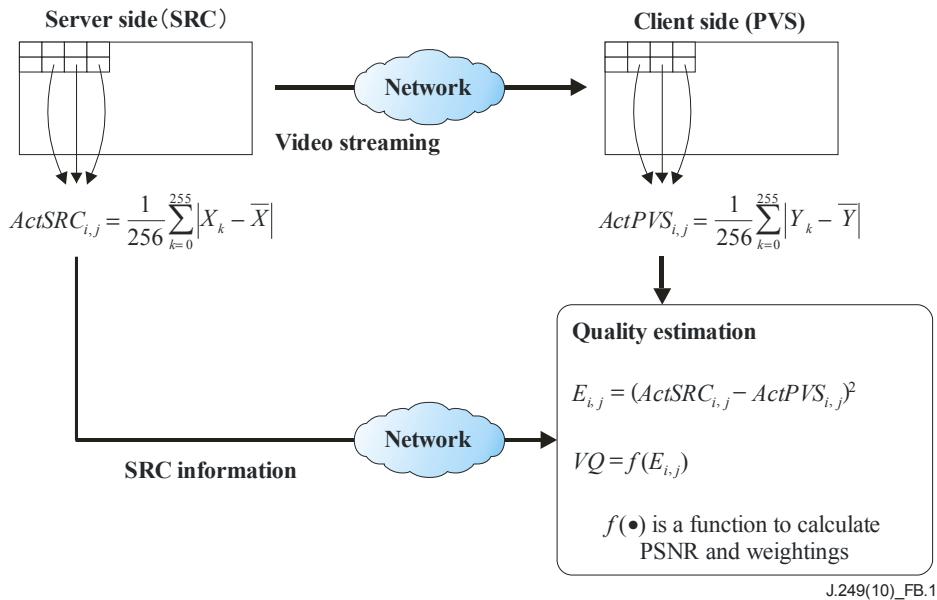

Figure B.1 – Video quality estimation based on activity difference

B.4 Detailed algorithm

B.4.1 Server side

- 1) Luminance pixels of an SRC are divided into 16x16 pixel blocks in each frame after one second from the top of the video sequence. In the first one second, the SRC information is not transmitted since it is difficult for the human visual system to detect video quality degradation in the scenes immediately after the first frame.
- 2) In each block except for those in the frame rim, the activity values (SRC activity: $ActSRC_{i,j}$) are calculated. Figure B.2 describes the blocks for which the activity values are calculated and transmitted. The SRC activity is calculated as:

$$ActSRC_{i,j} = \frac{1}{256} \sum_{k=0}^{255} |X_k - \bar{X}|$$

where X_k is a luminance value in a given-size block of the SRC, \bar{X} is its average, i is a frame number, and j is a block number in the frame.

- 3) Activity values, which are expressed with eight bits per block, are transmitted to the client side in the raster scan order after one second from the top of the video sequence. For SRC information transmission at a rate of 256 kbit/s, the activity values are transmitted in all frames. When the rate is reduced to 80 kbit/s, the activity values are transmitted in every four frames.

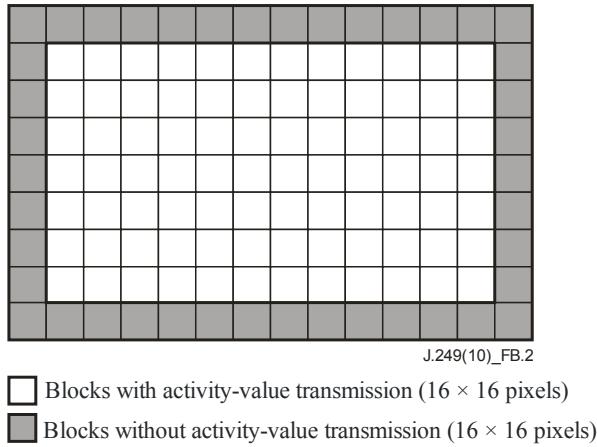

Figure B.2 – Blocks with and without activity value transmission

B.4.2 Client side

B.4.2.1 Squared error calculation of the activity values

- 1) Luminance pixels of a PVS are divided into 16x16 pixel blocks in each frame after one second from the top of the video sequence.
- 2) In each block except for those in the frame rim, the activity values (PVS activity: $ActPVS_{i,j}$) are calculated. At a rate of 256 kbit/s of SRC information, the activity values are calculated in all frames. When the rate of SRC information is reduced to 80 kbit/s, the activity values are calculated in every four frames.

$$ActPVS_{i,j} = \frac{1}{256} \sum_{k=0}^{255} |Y_k - \bar{Y}|$$

where Y_k is a luminance value in a given-size block of the PVS, \bar{Y} is its average, i is a frame number, and j is a block number in the frame.

- 3) Squared errors between the SRC activity and the PVS activity are calculated as:

$$E_{i,j} = (ActSRC_{i,j} - ActPVS_{i,j})^2$$

B.4.2.2 Psychovisual weighting for the squared error

Three kinds of weightings, namely, weighting for the difference in spatial frequency, weighting for the difference in the specific colour region, and weighting for the inter-frame difference of luminance, are applied to $E_{i,j}$ to take into account the human visual system characteristics.

- 1) Weighting for the difference in spatial frequency

A weighting factor W_{SF} and a threshold Th_{SF} are used for this weighting (see Table B.1 for the values of W_{SF} and Th_{SF}).

$$E_{i,j} \Leftarrow \begin{cases} E_{i,j} \times W_{SF}, & ActPVS_{i,j} > Th_{SF} \\ E_{i,j}, & otherwise \end{cases}$$

- 2) Weighting for the difference in the specific colour region

For a given block and its surrounding eight blocks, if the number of pixels ($NumROIPixels$) within $48 \leq Y \leq 224$, $104 \leq Cb \leq 125$ and $135 \leq Cr \leq 171$ is larger than a threshold, the following weighting is performed using a weighting factor W_{CR} and a threshold Th_{CR} .

$$E_{i,j} \leftarrow \begin{cases} E_{i,j} \times W_{CR}, & \text{NumROIPixels} > Th_{CR} \\ E_{i,j}, & \text{otherwise} \end{cases}$$

See Table B.1 for W_{CR} and Th_{CR} values.

3) Weighting for the inter-frame difference of luminance

Mean absolute difference ($MAD_{i,j}$) of the luminance between a given block and that in the previous frame is calculated. $MAD_{i,j}$ is defined as:

$$MAD_{i,j} = \frac{1}{256} \sum_{k=0}^{255} |Y_k - Y'_k|,$$

where Y_k is a luminance value in a 16x16 pixel block of the PVS and Y'_k is a luminance value in the same position in the previous frame. The following weighting is performed using weighting factors W_{MAD1} , W_{MAD2} and thresholds Th_{MAD1} , Th_{MAD2} .

$$E_{i,j} \leftarrow \begin{cases} E_{i,j} \times W_{MAD1}, & MAD_{i,j} > Th_{MAD1} \\ E_{i,j} \times W_{MAD2}, & MAD_{i,j} \leq Th_{MAD2} \\ E_{i,j}, & \text{otherwise} \end{cases}$$

See Table B.1 for W_{MAD1} , W_{MAD2} , Th_{MAD1} and Th_{MAD2} values.

B.4.2.3 Weighting in case of scene change detection

An average of $MAD_{i,j}$ ($MADAv_{e_i}$) is calculated for each frame as

$$MADAv_{e_i} = \frac{1}{M} \sum_{j=0}^{M-1} MAD_{i,j}$$

where M is the number of blocks in a frame.

If $MADAv_{e_i}$ is larger than a threshold Th_{SC} , it is considered as a scene change. When a scene change is detected, $E_{i,j}$ is set to 0 for 15 frames after the scene change.

$$\begin{aligned} SceneChange &= \begin{cases} \text{TRUE}, & MADAv_{e_i} > Th_{SC} \\ \text{FALSE}, & \text{otherwise} \end{cases} \\ E_{i,j} &\leftarrow \begin{cases} E_{ij} \times W_{SC}, & 15 \text{ frames after } SceneChange = \text{TRUE} \\ E_{i,j}, & \text{otherwise} \end{cases} \end{aligned}$$

See Table B.1 for W_{SC} and Th_{SC} values.

B.4.2.4 PSNR based on the squared error of the activity

A PSNR is calculated based on the activity-difference as:

$$VQ = 10 \times \log_{10} \frac{255 \times 255}{E_{Ave}}$$

$$E_{Ave} = \frac{1}{N \times M} \sum_{i=0}^{N-1} \sum_{j=0}^{M-1} E_{i,j}$$

where N and M are the number of frames and blocks used for the PSNR calculation.

B.4.2.5 Weighting for blockiness artefacts

A weighting factor W_{BL} , a threshold Th_{BL} and blockiness level information BL_{Ave} are used for this weighting (see Table B.1 for W_{BL} and Th_{BL} values).

$$VQ \leftarrow \begin{cases} VQ \times W_{BL}, & BL_{Ave} > Th_{BL} \\ VQ, & otherwise \end{cases}$$

BL_{Ave} is calculated by the following steps.

- 1) Activity values for 8x8 pixel blocks in a PVS are calculated. As shown in Figure B.3, the average value (Act_{Ave}) of the two activity values in horizontally adjacent blocks ($ActBlock_1, ActBlock_2$) is calculated by:

$$Act_{Ave} = \frac{1}{2}(ActBlock_1 + ActBlock_2)$$

- 2) The absolute difference of the luminance values along the boundary between two blocks is calculated. As illustrated in Figure B.3, $Y_{1,0}$ and $Y_{2,0}$ represent luminance values in the left and right blocks along the boundary. An average value of the absolute luminance difference, $DiffBound$, is expressed as:

$$DiffBound = \frac{1}{8} \sum_{i=0}^7 |Y_{1,i} - Y_{2,i}|$$

- 3) Blockiness level ($BL_{i,j}$) is defined by the ratio between $DiffBound$ and Act_{Ave} , i.e.:

$$BL_{i,j} = \frac{DiffBound}{Act_{Ave} + 1}$$

- 4) The average value of the BL is calculated by:

$$BL_{Ave} = \frac{1}{N \times M} \sum_{i=0}^{N-1} \sum_{j=0}^{M-1} BL_{i,j}$$

For the blocks in the rightmost in the frames, the $BL_{i,j}$ value is set to zero. If BL_{Ave} is larger than a pre-determined threshold, it is considered that the video sequence includes a high level of blockiness and weighting is applied to the calculated video-quality value.

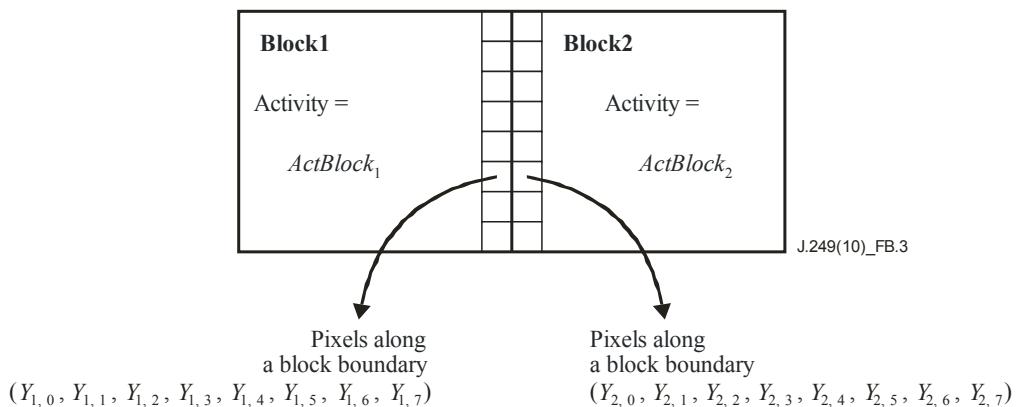

Figure B.3 – Pixel and activity values used for calculating blockiness level

B.4.2.6 Weighting for local impairment artefacts

A weighting factor W_{LI} , a threshold Th_{LI} and local impairment LI are used for this weighting (see Table B.1 for W_{LI} and Th_{LI} values).

$$VQ = \begin{cases} VQ \times W_{LI}, & LI < Th_{LI} \\ VQ, & \text{otherwise} \end{cases}$$

See Table B.1 for W_{LI} and Th_{LI} values.

LI is calculated by the following steps. The difference of the activity-variance is used to detect local impairment by transmission errors.

- 1) For a given block and its surrounding eight blocks, the variance of the activity is calculated for both the SRC ($ActVar_{SRC}$) and the PVS ($ActVar_{PVS}$) and the absolute difference of these variance values is calculated as:

$$\Delta ActVar = |ActVar_{SRC} - ActVar_{PVS}|$$

- 2) The average value of these absolute difference values is calculated for each frame.
- 3) LI is calculated as the ratio of the maximum ($\Delta ActVar_{Max}$) to the minimum ($\Delta ActVar_{Min}$) of the average:

$$LI = \begin{cases} \Delta ActVar_{Min} / \Delta ActVar_{Max}, & \Delta ActVar_{Max} \neq 0 \\ 1, & \Delta ActVar_{Max} = 0 \end{cases}$$

VQ represents the video quality score.

B.4.2.7 Parameters for the weightings

Table B.1 shows the parameter values for the weightings. These values are determined by a preliminary experiment with a training data set.

Table B.1 – Parameters for the weightings

Weighting operation type	Parameter values	
Spatial frequency weighting	W_{SF}	0.36
	Th_{SF}	25
Specific colour weighting	W_{CR}	4.0
	Th_{CR}	175
Inter-frame difference weighting	$W_{MAD 1}$	0.06
	$Th_{MAD 1}$	17
	$W_{MAD 2}$	25
	$Th_{MAD 2}$	13
Scene change detection	W_{SC}	0.0
	Th_{SC}	35
Blockiness weighting	W_{BL}	0.870
	Th_{BL}	1.0
Local impairment weighting	W_{LI}	0.870
	Th_{LI}	1.67

B.4.2.8 Registration

1) Spatial registration.

The NEC RR model does not need any spatial registration. This is because the squared error is calculated based on the activity values that are more robust to spatial shifts than those based on the pixel values.

2) Gain-and-offset registration.

The NEC RR model does not need gain-and-offset registration. The activity values are inherently free from the offset (i.e., DC components) and insensitive to the gain.

3) Temporal registration.

The PVS sequence is divided into 1-second sub-sequences. For each sub-sequence, the mean squared errors of the activity are calculated with five delay variations of up to ± 2 SRC frames. The minimum value of the mean squared errors is finally used as the mean squared error in this sub-sequence. The delay that results in this minimum mean squared error is adjusted as temporal registration.

B.5 Analysis of the results

The final report on the VQEG RRNR-TV model states that the performance of the NEC model is statistically equivalent to that of PSNR in the 525-line video format. In case of the 625-line video format, however, the performance of the NEC model is lower than that of PSNR. The correlation coefficients for the 625-line video format are 0.675 at 256 kbit/s and 0.653 at 80 kbit/s. This is caused by HRC9, which crops the frame rim in the SRC frames by replacing the original pixels with black ones. The NEC model had an inappropriate area for activity value calculation for the PVSs, resulting in undercropping.

If PVSs by HRC9 had not been accounted for, the correlation coefficient would have been 0.800 at 256 kbit/s and 0.781 at 80 kbit/s. These correlation coefficients are statistically equivalent to those of PSNR. This problem no longer exists by excluding the activity values within two blocks from the frame rim. In this case, the correlation coefficient is 0.828 at 256 kbit/s and 0.798 at 80 kbit/s. These facts indicate that the NEC model is equivalent in performance to PSNR both in the 525-line and the 625-line video formats.

B.6 Sample codes

C-language sample codes for the NEC RR model are provided here.

B.6.1 Common code, both server and client sides

```
// Calculate the activity value
unsigned int CalcActivitybyRect(unsigned char * lpBuffer, int nWidth, int
iRectWidth, int iRectHeight)
{
    // lpBuffer: Luminance Frame Buffer
    // nWidth: Frame Buffer Width
    // iRectWidth: Width of the rectangle to calculate an activity value.
    // iHeightWidth: Height of the rectangle to calculate an activity
    // value.
    unsigned int i, j, nTmp, nSum;
    unsigned char *pSrc;

    pSrc = lpBuffer;    nSum = 0;
    for (j = 0; j < iRectHeight; j++) {
        for (i = 0; i < iRectWidth; i++) {
            nSum += pSrc[i];
        }
        pSrc += nWidth;
```

```

        }
        nSum /= (iRectWidth*iRectHeight);

        pSrc = lpBuffer; nTmp = 0;
        for (j = 0; j < iRectHeight; j++) {
            for (i = 0; i < iRectWidth; i++) {
                nTmp += abs(pSrc[i] - nSum);
            }
            pSrc += nWidth;
        }
        return nTmp/iRectWidth/iRectHeight;
    }
}

```

B.6.2 Server side

```

// Server side
int nStart = 30; // the frame number to start transmission (30 or 25)
int nMaxFrame = 240; // the number of total video frames (240 or 200)
int nFrameIncrement = 1; // 1 for 256kbps, 4 for 80kbps
void ReadOneFrame(unsigned char, int, unsigned char *, int, int); // function to
// read one frame data
int nRim = 16 // 16 or 32 (use 32 to avoid the problem in HRC9)

// nWidth: Frame Buffer Width
// nHeight: Frame Buffer Height
// lpSrc: Frame Buffer
for(int nFrame = nStart; nFrame < nMaxFrame; nFrame+=nFrameIncrement) {
    ReadOneFrame(SRC_file_name, nFrame, lpSrc, nWidth, nHeight);
    for (j= 16; j<nHeight-32; j+=16) {
        for (i= nRim; i<nWidth- nRim; i+=16) {
            lpOrg = lpSrc + i + j * nWidth;
            nActSrc = CalcActivitybyRect(lpOrg, nWidth, 16, 16);

B.7 Informative reference

[b-SMPTE 170M] SMPTE 170M (2004), *Television – Composite Analog Video Signal – NTSC for Studio Applications.*

Annex C

Model_C: NTIA (80 kbit/s model)

(This annex forms an integral part of this Recommendation)

C.1 Background

In the 2003-2004 time frame, the U.S. National Telecommunications and Information Administration (NTIA) developed two video quality models (VQMs) with a reduced reference (RR) bandwidth of approximately 12 to 14 kbit/s for Recommendation ITU-R BT.601 sampled video [b-ITU-R BT.601-6]. These models were called the "low bandwidth VQM" and "fast low bandwidth VQM". The fast low bandwidth VQM was a computationally efficient version of the low bandwidth VQM. The fast low bandwidth VQM is about 4 times faster since it extracts spatial features from video frames that are first pre-averaged, rather than extracting spatial features directly from the ITU-R 601 video frames. Additional computational savings for the fast low bandwidth VQM resulted from computing temporal information (i.e., motion) features based on a random sub-sampling of pixels in the luminance Y channel rather than using all pixels in all three video channels (Y, Cb and Cr). Both VQMs have been available in the NTIA VQM software tools for several years and may be freely used for both commercial and non-commercial applications. Binary executable versions of these VQM tools and their associated source code are available for download [b-NTIA].

Since NTIA wanted to submit both the low bandwidth and fast low bandwidth VQMs to the reduced reference TV (RRTV) tests for independent evaluation by the video quality experts group (VQEG), NTIA chose to submit them to different bit rate categories even though they have identical RR bit rate requirements. NTIA chose to submit the low bandwidth VQM to the 256k category and the fast low bandwidth VQM to the 80k category since the performance of the low bandwidth VQM was expected to be superior to that of the fast low bandwidth VQM. Both VQMs utilized the NTIA RR calibration algorithm which is included in [ITU-T J.244]. This calibration algorithm requires approximately 22 to 24 kbit/s of RR bandwidth to produce estimates for temporal delay, spatial shift, spatial scaling, gain and level offset.

An interesting result from the VQEG RRTV evaluation tests [b-VQEG MM] was that the fast low bandwidth VQM outperformed the low bandwidth VQM for both the 525-line and 625-line tests. This is an interesting result since it implies that extracting spatial features from averaged frames is superior to extracting them from non-averaged frames. Whether or not this result will prove true for other data sets is an area for further research. At this time, NTIA does not see a reason to standardize both models, so this annex only describes the fast low bandwidth VQM.

C.2 Introduction

This annex presents a description and reference code for the NTIA fast low bandwidth VQM. The NTIA fast low bandwidth VQM utilizes techniques similar to those of the NTIA general VQM, a description of which can be found in both [ITU-T J.144] and [b-ITU-R BT.1683]. The fast low bandwidth VQM uses RR features with much less bandwidth than the NTIA general VQM, but the feature extraction and comparison process is similar for both. For ITU-R BT.601 sampled video [b-ITU-R BT.601-6], the fast low bandwidth VQM uses RR features that require approximately 12 to 14 kbit/s of transmission bandwidth. This annex only describes the fast low bandwidth VQM since its complementary low bandwidth calibration algorithms are fully documented in [ITU-T J.244]. However, for completeness, the reference code in this annex includes both the fast low bandwidth VQM and its associated low bandwidth calibration algorithms. The reference code also contains example quantization functions for the features used by the low bandwidth calibration (these quantization functions are not part of [ITU-T J.244]).

C.3 Fast low bandwidth VQM description

C.3.1 VQM overview

The VQM description will encompass three primary areas: 1) the low bandwidth features that are extracted from the original and processed video streams; 2) the parameters that result from comparing like original and processed feature streams; and 3) the VQM calculation that combines the various parameters, each of which measures a different aspect of video quality. This description makes use of readily available references for the technical details.

C.3.2 Feature description

C.3.2.1 Feature overview

Three types of features are used by the fast low bandwidth VQM: colour, spatial and temporal. Each of these feature types quantify perceptual distortions in their respective domains. The reference code subroutine "model_fastlowbw_features" provides a complete mathematical description of the features used by the fast low bandwidth VQM.

C.3.2.2 Colour features

The colour features are the same f_{COHER_COLOR} features that are used by the NTIA general VQM. These features are described in detail in clause D.7.3 of [ITU-T J.144]. The f_{COHER_COLOR} features provide a two-dimensional vector measurement of the amount of blue and red chrominance information (C_B , C_R) in each spatial-temporal (S-T) region. Thus, the f_{COHER_COLOR} features are sensitive to colour distortions. The f_{COHER_COLOR} features of the NTIA fast low bandwidth VQM are extracted from S-T region sizes of 30 vertical lines by 30 horizontal pixels by 1 second of time (i.e., $30 \times 30 \times 1\text{s}$), whereas the NTIA general VQM used S-T region sizes of $8 \times 8 \times 1\text{ frame}$.

C.3.2.3 Spatial features

The spatial features are the same f_{SII3} and f_{HVI3} features that are used by the NTIA general VQM. These features are described in detail in clause D.7.2.2 of [ITU-T J.144]. The f_{SII3} and f_{HVI3} features measure the amount and angular distribution of spatial gradients in S-T sub-regions of the luminance (Y) images. Thus, the f_{SII3} and f_{HVI3} features are sensitive to spatial distortions such as blurring and blocking.

The f_{SII3} and f_{HVI3} features of the NTIA fast low bandwidth VQM are extracted from S-T region sizes of 30 vertical lines by 30 horizontal pixels by 1 second of time (i.e., $30 \times 30 \times 1\text{s}$) whereas the NTIA general VQM used S-T region sizes of $8 \times 8 \times 0.2\text{s}$. In addition, to save computations, the 1 second of luminance Y images are first pre-averaged across time before applying the two-dimensional 13×13 edge enhancement filters given in clause D.7.2.1 of [ITU-T J.144].

One additional spatial feature is extracted from the 1 second of pre-averaged luminance (Y) images. This feature is the *mean* luminance (Y) level of each $30 \times 30 \times 1\text{s}$ S-T region (denoted here as f_{MEAN}). The purpose of the f_{MEAN} feature is to provide a luminance-level perceptual weighting function for spatial information (SI) loss as measured by the f_{SII3} and f_{HVI3} features. This will be described in clause C.3.3.

C.3.2.4 Temporal features

Powerful estimates of perceived video quality can be obtained from the colour and spatial feature set described above. However, since the S-T regions from which these features are extracted span many video frames (i.e., 1 second of video frames), they tend to be insensitive to brief temporal disturbances in the picture. Such disturbances can result from noise or digital transmission errors and, while brief in nature, they can have a significant impact on the perceived picture quality. Thus, a temporal-based RR feature is used to quantify the perceptual effects of temporal disturbances. This feature measures the absolute temporal information (ATI), or motion, in the luminance Y image plane and is computed as:

$$f_{ATI} = \text{rms}\{\text{rand}5\%|Y(t) - Y(t - 0.2s)|\}$$

For computational efficiency, Y is randomly sub-sampled to contain only 5% of the image pixels (represented here by the *rand5%* function). The sub-sampled Y image at time $t-0.2s$ is subtracted from the identically sub-sampled Y image at time t and the root mean square error (*rms*) of the result is used as a measure of ATI. Using the convention found in clause D.8 of [ITU-T J.144], this will also be denoted as:

$$f_{ATI} \cong Y_rand5\%_ati0.2s_rms$$

The feature f_{ATI} is sensitive to temporal disturbances. For 30 fps video, 0.2 s is six video frames while for 25 fps video, 0.2 s is five video frames. Subtracting images 0.2 s apart makes the feature insensitive to real time 30 fps and 25 fps video systems that have frame update rates of at least 5 fps. The quality aspects of these low frame rate video systems, common in multimedia applications, are sufficiently captured by the f_{SI13} , f_{HVI3} and f_{COHER_COLOR} features. The 0.2 s spacing is also more closely matched to the peak temporal response of the human visual system than differencing two images that are one frame apart in time.

Figure C.1 provides an example plot of the f_{ATI} feature for a original (solid blue) and processed (dashed red) video scene from a digital video system with transient burst errors in the digital transmission channel. Transient errors in the processed picture create spikes in the f_{ATI} feature. The bandwidth required to transmit the f_{ATI} feature is extremely low since it requires only 30 samples per second for 30 fps video. Other types of additive noise in the processed video, such as might be generated by an analogue video system, will appear as a positive DC shift in the time history of the processed feature stream with respect to the original feature stream. Video coding systems that eliminate noise will cause a negative DC shift.

Before extracting a transient error parameter from the f_{ATI} feature streams shown in Figure C.1, it is advantageous to increase the width of the motion spikes (dashed red spikes in Figure C.1). The reason is that short motion spikes from transient errors do not adequately represent the perceptual impact of these types of errors. One method for increasing the width of the motion spikes is to apply a maximum filter to both the original and processed feature streams before calculation of the error parameter function between the two waveforms. For the f_{ATI} -based error parameter, a 7-point wide maximum filter (which will be denoted here as the *max7pt* function) was used that produces an output sample at each frame that is the maximum of itself and the 3 nearest neighbours on each side (i.e., earlier and later time samples).

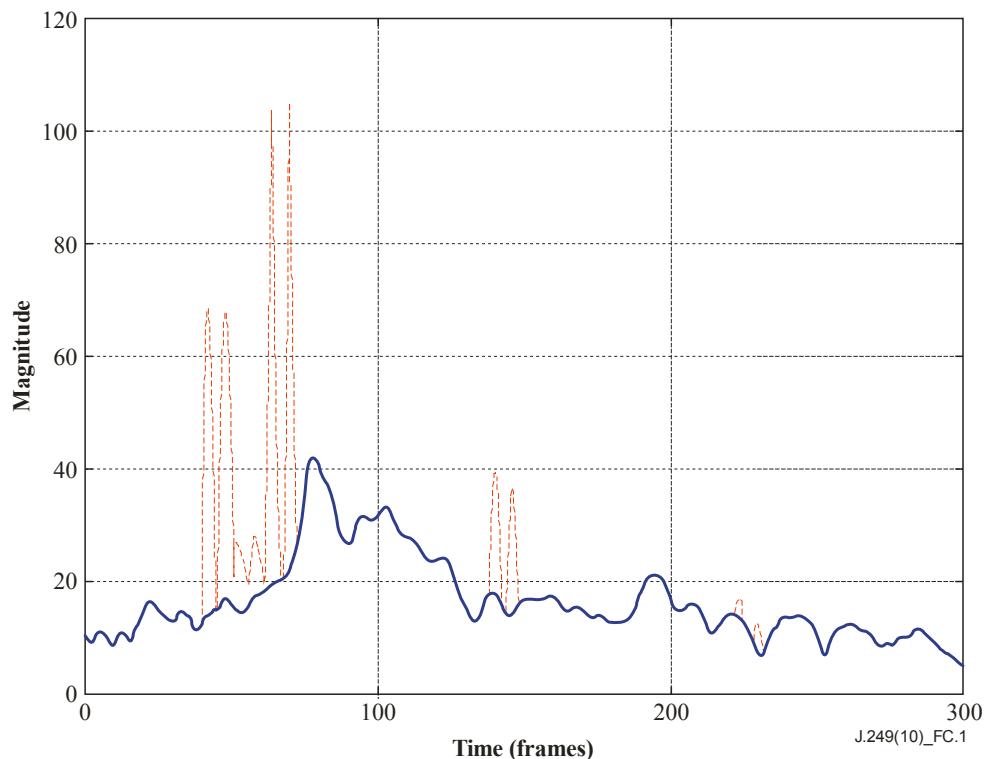

Figure C.1 – Example time history of f_{ATI} feature

C.3.2.5 Quantization of features

Quantization to 9 bits of accuracy is sufficient for the Y_{MEAN} , f_{SII3} , f_{HVI3} and f_{COHER_COLOR} features, while the f_{ATI} feature should be quantized to 10 bits. To have minimal effect on the video quality parameter calculations, a non-linear quantizer design should be used where the quantizer error is proportional to the magnitude of the signal being quantized. Very low values are uniformly quantized to some cut-off value, below which there is no useful quality assessment information. Such a quantizer design minimizes the error in the corresponding parameter calculations because these calculations are normally based on an error ratio or log ratio of the processed and original feature streams (see the parameter description in clause C.3.3).

Figure C.2 provides a plot of the 9-bit non-linear quantizer used for the f_{SII3} original feature. The reference code subroutine "model_lowbw_compression" provides a complete mathematical description of the recommended quantizers used by the fast low bandwidth VQM. If the features fall outside the range of the recommended quantizers on the low or high end (highly unlikely), then the S-T parameters derived from these features are zeroed so they do not influence the overall VQM.

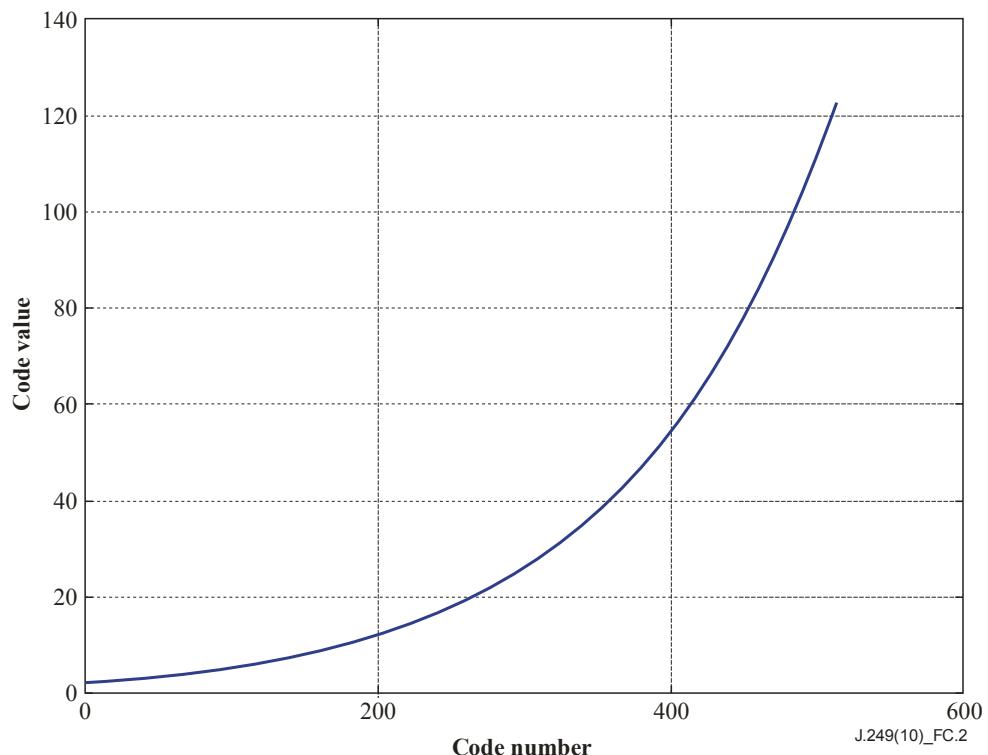

Figure C.2 – Non-linear 9-bit quantizer for the f_{SII3} feature

C.3.3 Parameter description

C.3.3.1 Parameter overview

Several steps are involved in the calculation of parameters that track the various perceptual aspects of video quality. The steps may involve: 1) applying a perceptual threshold to the extracted features from each S-T sub-region; 2) calculating an error function between processed features and corresponding original features; and 3) pooling the resultant error over space and time. See clause D.8 of [ITU-T J.144] for a detailed description of these techniques and their accompanying mathematical notation for parameter names, which are also used here. The reference code subroutine "model_fastlowbw_parameters" provides a complete mathematical description of the parameters used by the fast low bandwidth VQM. For simplicity, the description of the parameters in this clause does not consider the effects of feature quantization (e.g., handling feature values that might lie outside of the recommended quantization ranges).

C.3.3.2 New methods

This clause summarizes new methods that have been found to improve the objective-to-subjective correlation of parameters based on RR features with very low transmission bandwidths, such as those utilized for the NTIA fast low bandwidth VQM (i.e., new methods not found in [ITU-T J.144]). It is worth noting that no improvements have been found for the basic form of the parameter error functions given in clause D.8.2.1 of [ITU-T J.144]. The two error functions that consistently produce the best parameter results (for spatial and temporal parameters) are a logarithmic ratio $\{\log_{10} [f_p(s,t)/f_o(s,t)]\}$ and an error ratio $\{[f_p(s,t) - f_o(s,t)]/f_o(s,t)\}$, where $f_p(s,t)$ and $f_o(s,t)$ are the processed feature and corresponding original feature extracted from the S-T region with spatial coordinates s and temporal coordinates t , respectively. Errors must be separated into gains and losses, since humans respond differently to additive (e.g., blocking) and subtractive (e.g., blurring) impairments. Applying a lower perceptual threshold to the features before application of these two error functions prevents division by zero.

After computation of the S-T parameters using one of the error functions, then the S-T parameters must be pooled over space and time to produce a parameter value for the video clip. This error

pooling can occur in multiple stages (e.g., over space and then over time). One new error pooling method that is utilized by the fast low bandwidth VQM is called macro-block (MB) error pooling. MB error pooling groups a contiguous number of S-T sub-regions and applies an error pooling function to this set. For instance, the function denoted as "MB(3,3,2)max" will perform a max function over parameter values from each group of 18 S-T sub-regions that are stacked 3 vertical by 3 horizontal by 2 temporal. For the 32 x 32 x 1s S-T sub-regions of the f_{SI13} , f_{HV13} and f_{COHER_COLOR} features described above, each MB(3,3,2) region would encompass a portion of the video stream that spans 96 vertical lines by 96 horizontal pixels by 2 seconds of time. MB error pooling has been found to be useful in tracking the perceptual impact of impairments that are localized in space and time. Such localized impairments often dominate the quality decision process. MB error pooling can also be implemented as a filtering process so that instead of producing a single output value for each MB, each S-T sample is replaced with its MB filtered value, where the MB is centred on the S-T sample. This is called overlapped MB (OMB) error pooling.

A second error pooling method is a generalized Minkowski(P,R) summation, defined as:

$$Minkowski(P, R) = \sqrt[R]{\frac{1}{N} \sum_{i=1}^N |v_i|^P}$$

Here, v_i represents the parameter values that are included in the summation. This summation might, for instance, include all parameter values at a given instance in time (spatial pooling), or may be applied to the macro-blocks described above. The Minkowski summation where the power P is equal to the root R has been used by many developers of video quality metrics for error pooling. The generalized Minkowski summation, where $P \neq R$, provides additional flexibility for linearizing the response of individual parameters to changes in perceived quality. This is a necessary step before combining multiple parameters into a single estimate of perceived video quality, which is performed with a linear fit.

C.3.3.3 Colour Parameters

Two parameters are extracted from the f_{COHER_COLOR} features. One of these parameters, called *color_extreme*, measures extreme colour distortions that might be caused by coloured blocks from transmission errors. The other parameter, called *color_spread*, provides an indication of the variance or spread in the colour errors. Rather than using the Euclidean distance measure to quantify distortions (as in clause D.8.2.2 of [ITU-T J.144]), both of these parameters use the square root of the Manhattan distance. Following the mathematical notation in clause D.8.2.2 of [ITU-T J.144], where $f_p(s,t)$ and $f_o(s,t)$ represent the 2-dimensional f_{COHER_COLOR} feature extracted from an S-T region of the processed and original video streams, this feature comparison function is given by:

$$\text{sqrtmanhat}(s,t) = \sqrt{\sum_{C_B, C_R} |f_p(s,t) - f_o(s,t)|}$$

The Manhattan distance measure seems to be better than the Euclidean distance measure and the square root function is required to linearize the parameter's response to quality changes. Following the mathematical notations in clause D.8 of [ITU-T J.144], the colour parameters are given by:

$$\begin{aligned} \text{color_extreme} &= \text{color_coher_color_30x30_1s_mean_sqrtmanhat_OMB}(3,3,2)\text{above99\%}_\text{Minkosski}(0.5,1) \\ \text{color_spread} &= \text{color_coher_color_30x30_1s_mean_sqrtmanhat_OMB}(3,3,2)\text{Minkosski}(2,4)_90\% \end{aligned}$$

A combined colour parameter (*color_comb*) that contains the optimal combination of both the *color_extreme* and *color_spread* parameters is then computed as:

$$\text{color_comb} = 0.691686 * \text{color_extreme} - 0.617958 * \text{color_spread}$$

This positive valued *color_comb* parameter is then clipped at the low end, which is represented mathematically by (following the notation in clause D.8.5 of [ITU-T J.144]):

$$\text{color_comb} = \text{color_comb_clip_0.114}$$

This *color_comb* parameter is included in the linear combination for the VQM calculation.

C.3.3.4 Spatial parameters

Two spatial parameters are computed from the f_{SI13} feature, one that measures a loss of spatial information (*si_loss*) and one that measures a gain of spatial information (*si_gain*). Following the mathematical notation in clause D.8 of [ITU-T J.144], these parameters are given by:

$$\begin{aligned} \text{si_loss} &= \text{avg1s_Y_si13_30x30_std_3_ratio_loss_OMB}(3,2) \text{Minkowski}(1,2) \text{Minkowski}(1.5,2.5) \text{clip_0.12} \\ \text{si_gain} &= \text{avg1s_Y_si13_30x30_std_3_log_gain_clip_0.1_above95\%tail_Minkowski}(1.5,2) \end{aligned}$$

As the mean luminance (Y) level of the S-T sub-region increases (i.e., as measured by the f_{MEAN} feature), the ability to perceive changes in spatial detail (e.g., such as blurring measured by *si_loss*) decreases. This can be accommodated by introducing a weighting function (*Y_weight*) as shown in Figure C.3 to the *si_loss* values from each S-T sub-region (i.e., the *si_loss* values after the ratio loss comparison function is performed on each S-T sub-region but before the spatial and temporal collapsing functions). The weighting function *Y_weight* is equal to one (i.e., full weighting) until an average luminance level of 175 is reached and then it decreases linearly to zero as the luminance values increase from 175 to 255. This intermediate correction is applied only to the *si_loss* values, not the *si_gain* values.

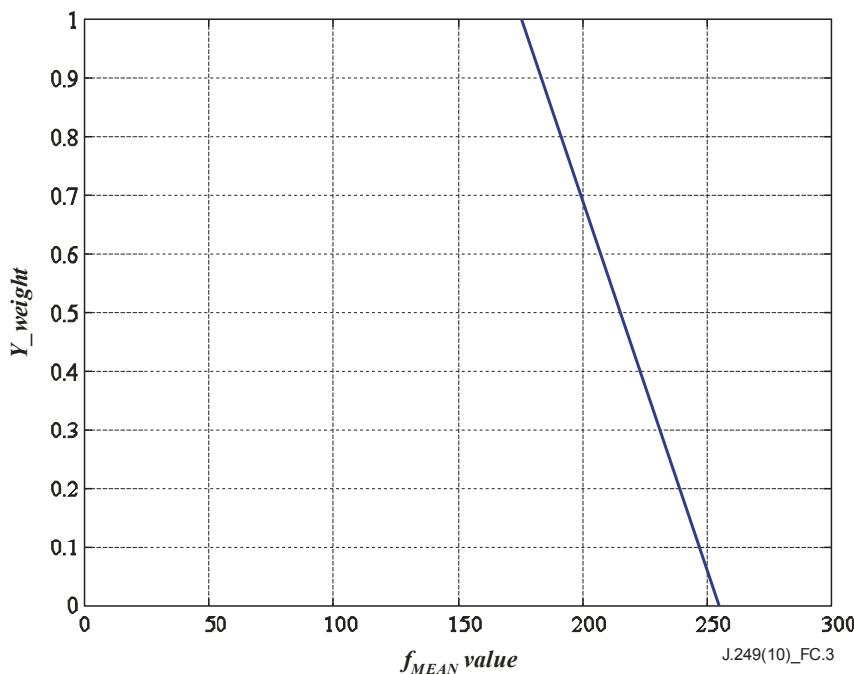

Figure C.3 – Weighting function *Y_weight* for modifying *si_loss* S-T parameters

Two spatial parameters are computed from the f_{HVI3} feature, one that measures a loss of relative horizontal and vertical (HV) spatial information (*hv_loss*) and one that measures a gain (*hv_gain*). Following the mathematical notation in clause D.8 of [ITU-T J.144], these parameters are given by:

$$\begin{aligned} \text{hv_loss} &= \text{avg1s_Y_hvl3_angle0.225_rmin20_30x30_mean_4_ratio_loss_...} \\ &\quad \text{OMB}(3,3,2)\text{below1\%}_\text{Minkowski}(1,1.5)\text{clip_0.08} \end{aligned}$$

```

hv_gain = avg1s_Y_hv13_angle0.225_rmin20_30x30_mean_4_log_gain_...
clip_0.06_OMB(3,3,2)above99%tail_Minkowski(1.5,3)

```

Not shown in the above equations is that the *Y_weight* function shown in Figure C.3 is also applied to both the *hv_loss* and *hv_gain* values from each S-T sub-region before the spatial and temporal collapsing functions (after the ratio_loss and log_gain computations, respectively). An additional weighting function (*SI_weight* as shown in Figure C.4) is applied to the *hv_loss* values from each S-T sub-region. This was necessary to reduce the sensitivity of *hv_loss* for S-T regions that have very little spatial information (i.e., low f_{SI13} original feature values).

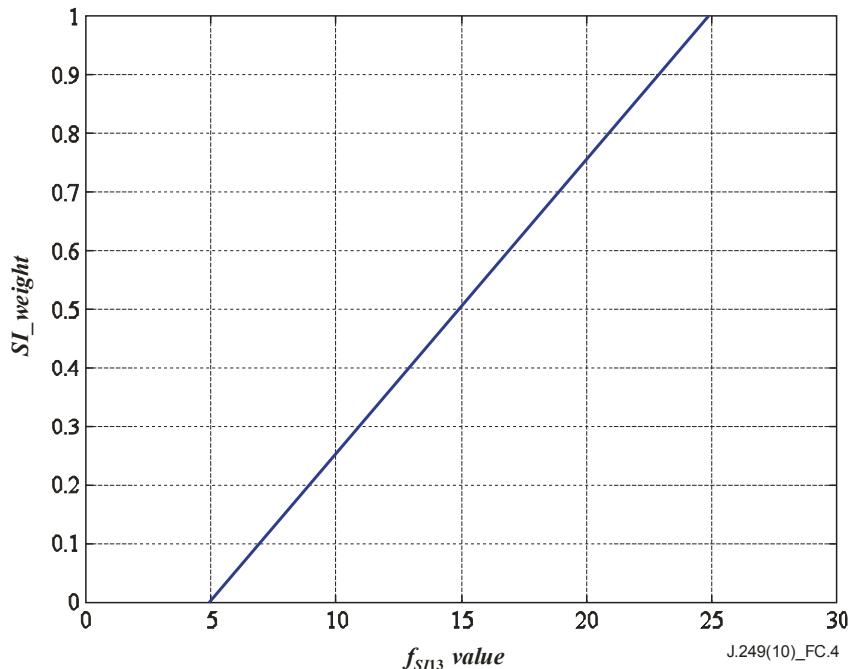

Figure C.4 – Weighting function *SI_weight* for modifying *hv_loss* S-T parameters

The spatial distortion parameters can be crushed (i.e., excessive excursions beyond those found in the training data are limited or compressed) using functions like the VQM crushing function found in clause C.3.4.

C.3.3.5 Temporal parameters

Two temporal parameters are computed from the f_{ATI} feature, one that measures added random noise (*ati_noise*) and one that measures motion disturbances caused by transmission errors (*ati_error*). Following the mathematical notation in clause D.8 of [ITU-T J.144], these parameters are given by:

$$ati_noise = Y_rand5\%_ati0.2s_rms_5_ratio_gain_between25\%50\%$$

$$ati_error = Y_rand5\%_ati0.2s_rms_max7pt_12_ratio_gain_above90\%$$

To make the *ati_noise* and *ati_error* parameters more robust against temporal misalignments, the parameters are computed for all temporal alignments of the processed video that are within plus or minus 0.4 seconds of the best estimated temporal alignment to the original video, and then the minimum parameter value is selected.

C.3.4 VQM calculation

Similar to the NTIA general VQM in Annex D of [ITU-T J.144], the fast low bandwidth VQM calculation linearly combines two parameters from the f_{HVI3} feature (*hv_loss* and *hv_gain*), two parameters from the f_{SI13} feature (*si_loss* and *si_gain*), and two parameters from the f_{COHER_COLOR}

feature (except that the two parameters have been combined into a single colour distortion parameter called *color_comb*). The one noise parameter in the NTIA general VQM has been replaced with two parameters based on the low bandwidth f_{ATI} feature described here (*ati_noise* and *ati_error*).

Thus, VQM_{FLB} (abbreviation for fast low bandwidth VQM) consists of a linear combination of eight parameters. VQM_{FLB} is given by:

$$VQM_{FLB} = \{ 0.38317338378290 * hv_loss + 0.37313218013131 * hv_gain + \\ 0.58033514546526 * si_loss + 0.95845512360511 * si_gain + \\ 1.07581708014998 * color_comb + \\ 0.17693274495002 * ati_noise + 0.02535903906351 * ati_error \}$$

The total VQM (after the contributions of all the parameters are added up) is clipped at a lower threshold of 0.0 to prevent negative VQM numbers. Finally, a crushing function that allows a maximum of 50% overshoot is applied to VQM values over 1.0 to limit VQM values for excessively distorted video that falls outside the range of the training data.

If $VQM_{FLB} > 1.0$, then $VQM_{FLB} = (1 + c) * VQM_{FLB} / (c + VQM_{FLB})$, where $c = 0.5$.

VQM_{FLB} computed in the above manner will have values greater than or equal to zero and a nominal maximum value of one. VQM_{FLB} may occasionally exceed one for video scenes that are extremely distorted.

To make VQM_{FLB} more robust against spatial misalignments, VQM_{FLB} is computed for all spatial alignments of the processed video that are within plus or minus one pixel of the best estimated spatial alignment to the original video, and then the minimum VQM_{FLB} is selected.

C.5 Reference code for implementing the fast low bandwidth VQM

The purpose of this reference code is to assist the user with proper implementation of the fast low bandwidth VQM. While MATLAB® code is used for the reference code, any software code can be used that reproduces the results given here. Each subclause within clause C.5 contains MATLAB code for the function named in the section header (e.g., save the contents of clause 5.1 to a file called "fastlowbw_ref.m"). Execute fastlowbw_ref with no arguments to receive help information on how to call the routine. This code contains the flexibility of running the model on a short video clip (i.e., 5 to 15 seconds) within a larger video sequence (e.g., one-minute sequence). This is done by shifting the short video clip by one second and re-computing the model for each temporal shift. While this functionality is not demonstrated below, comments within the code and returned arguments from "model_fastlowbw_parameters.m" will refer to this capability. This hidden capability may be useful for implementing an in-service video quality monitoring system.

When the sample test vectors (i.e., video clips) are processed with the fast low bandwidth VQM reference code (function "fastlowbw_ref.m"), text files are produced that contain the calibration and model results. For the following example MATLAB function calls, output files similar to those given below should be obtained (due to random processes used by the fast low bandwidth VQM, results may vary slightly from those presented here).

% NOTES FOR PROGRAMMERS:
%
% 1. To modify the temporal delay search range, change variable "uncert"
% passed into function dll_lowbw_temporal.m
%
% 2. To modify spatial shift and scaling search limits, change variables
% "max_shift_horiz", "max_shift_vert", "max_scale_horiz" and
% "max_scale_vert" at the beginning of function dll_lowbw_calib_processed.m
% and dll_lowbw_calib_original.m. These values must be identical for both
% functions, and are currently set automatically based on image size.
% Choosing larger values may make the algorithm unstable.
%
% 3. The original file is referred to by an ID of "1" throughout, and the
% processed file is referred to by an ID of "2". These are referred to
% within functions by the variable name "fn" (i.e., "F" for "file" and "N" for
% "number").
%
% 4. To separate into upstream and downstream parts, simply call each
% function requiring the original file ("1") into one piece, and the
% functions requiring the processed file ("2") into another piece. This
% code presumes downstream monitoring or bi-directional communication.
% Some of the functions require both processed video file and the original
% features and results from the previous steps.
%
% 5. If implementing a system that is entirely down-stream (i.e., no
% communication from processed to original), then the original will need to
% assume a valid region. Discarding the overscan is recommended (see also
% dll_default_vr.m).
%
% 6. The reduced reference calibration routines and model presented herein
% use some randomized processes. As a result, the results of this program
% will differ slightly from one run to the next. This variability can be
% prevented by initializing the random number generator with a constant
% value. This will aid debugging.
%
% 7. When comparing results from this implementation to results from
% BVQM, slight differences will be observed. These stem from the random
% number generator, yet also because BVQM performs filtering over the
% results from multiple video sequences. The places where filtering should
% be performed is mentioned in comments, below.

%

```
function [sroi,vert,horiz] = adjust_requested_sroi (struct, varargin)
% ADJUST_REQUESTED_SROI
% Adjust the requested Spatial Region of Interest (SROI) as specified.
% SYNTAX
% [sroi] = adjust_requested_sroi (struct)
% [sroi] = adjust_requested_sroi (...,'PropertyName',PropertyValue,...);
% [sroi,vert,horiz] = adjust_requested_sroi (...);
% DESCRIPTION
% Given clip 'struct' (in the same format as GClips or Gsscqe), return the
% adjusted spatial region of interest ('sroi'). Return variable is a
% structure, with four elements, 'roi.top', 'roi.left', 'roi.bottom',
% and 'roi.right'. NOTE: variable 'struct' uses only image_size and cvr.
%
% 'sroi',...      Requested spatial region of interest (SROI), overriding
%                 default values of SROI. Must be followed by 4 values,
%                 specifying the region of interest, in the order: top,
%                 bottom, left, right. SROI will be adjusted. Default
%                 SROI given by function 'default_sroi'.
% 'hsize', value, Horizontal size of S-T blocks. SROI must evenly divide
%                 by this value, horizontally.
% 'vsize', value, Vertically size of S-T blocks. SROI must evenly divide
%                 by this value, vertically.
% 'extra', value, This many valid pixels are required on all sides of the
%                 SROI, extra pixels for filtering. Returned SROI will
%                 NOT include those extra pixels!
% 'yxextra', y, x, Number 'y' indicates the number of valid pixels required
%                 on top and bottom sides of the SROI; number 'x' indicates
%                 the number of valid pixels required on the left and right
%                 of the SROI. Returned SROI will NOT include those extra
%                 pixels!
%
% Optional return arguments 'vert' and 'horiz' will, if present, be filled
% with the number of abutting blocks that fit vertically and
% horizontally within the SROI.
% REMARKS
% The top-left coordinate will be odd, and the bottom-right coordinate
% even. Thus, an equal number of pixels will be used from both fields.
%

C.5.27 Function "filter_si_hv_adapt.m"

```

function [si, hv, hvb] = filter_si_hv_adapt(y, filter_size, extra, varargin)
% FILTER_SI_HV_ADAPT
%
% Filters Y with the NxN gradient (c=2) filters described in SPIE 1999
% paper. Like function 'filter_si_hv', but can choose other than 13x13.
%
% SYNTAX
%
% [SI] = filter_si_hv_adapt(Y, N, EXTRA)
% [SI] = filter_si_hv_adapt(Y, N, EXTRA, rmin, theta)
% [SI, HV, HVB] = filter_si_hv_adapt(...)
%
% DESCRIPTION
%
% [SI] = filter_si_hv_adapt(Y, N, EXTRA) Perceptually filters luminance image
% Y using
% the NxN Horizontal and Vertical gradient filters in a fashion similar
% to the sobel filter. Discard the filtered border, of width EXTRA, where
% ( EXTRA >= floor(N/2) ). Filter size, N, must be an odd number.
%
% If Y is a 3 dimensional matrix, Y will be presumed to contain multiple
% images as follows: (row, col, time). No execution time penalties occur.
%
% [SI] = filter_si_hv(Y, N, EXTRA, rmin, theta) allows the user to override
% the default values for rmin and theta.
%
% [SI, HV, HVB] = filter_si_hv(...) returns three perceptually filtered
% versions of image Y: the SI filtered image, the HV filtered image
% (containing horizontal & vertical edges) and the HVB image (containing
% diagonal edges.)
%
% REMARKS
%
% rmin defaults to 20, where pixels with a radius (i.e., SI value) less
% than rmin are set to zero in HV and HVB images.
%
% Theta defaults to 0.225 radians. Theta is the maximum angle deviation
% from the H and V axis for pixels to be considered HV pixels.
%
% Returned images (SI, HV, and HVB) are the same size as Y; except that a
% border of EXTRA pixels around the edge of each image is invalid.

C.5.30 Function "model_fastlowbw_features.m"

```

function [si_std hv_ratio y_mean cb_mean cr_mean ati_rms] = ...
    model_fastlowbw_features (mode, one, two, three, four, five, six);
% MODEL_fastlowbw_features
% Compute the original features for the ITS fast low bandwidth model.
% SYNTAX
%     model_fastlowbw_features ('memory', y, cb, cr, fps, filter_size, extra);
%
% [si_std, hv_ratio, y_mean, cb_mean, cr_mean, ati_rms] = ...
%     model_fastlowbw_features ('eof');
%
% model_fastlowbw_features ('clear');
% DESCRIPTION
% When the first argument is the string 'memory', this function takes one
% second (EXACTLY) of video already in memory, in the YCbCr colorspace
% (y, cb, and cr respectively). All three variables are formatted
% (row,col,time); and (fps) is the number of frames per second (e.g.,
% 29.97, 30, 25, 15, etc). 'filter_size' and 'extra' are from function
% 'adaptive_filter' when given the current image size.
% Size of y, cb, & cr spatially should be exactly ROI returned by
% function model_lowbw_sroi. See 'eof'.
%
% When the first argument is the string 'eof', this function completes
% the feature calculations, empties internal buffers, and returns the
% feature stream. See 'memory'.
%
% When the first argument is the string 'clear', all internal buffers
% are emptied. This is done when 'eof' is called, also.
%
% Warning: uses 1 set of internal buffers, so don't mix sequences.
%
% Return variables when called with 'eof' are the six feature streams:

```

```

% - si_std containing standard deviation of the spatial information (SI)
% - hv_ratio containing the ratio of HV to HVbar energy
% - cb_mean containing the average Cb value
% - cr_mean containing the average Cr value
% - ati_rms containing the root mean squared of absolute value of
%   temporal information (TI)

```

% 'fps' is the frame rate of the video
% 'do_test_print' is 1 to print information and 0 typically.
% 'time_delta' is the number of seconds of video used to compute the
% FastLowBandwidth model. If you want a single prediction
% instead of a continuous history of values, then
% 'time_delta' should be the length of the video sequence in
% seconds, rounded down (e.g., the 3rd dimension of si_orig).
% 'time_delta' defaults to ten seconds (10). This is the
% recommended value. 'time_delta' should never be greater
% than 30 seconds, because different perceptual decisions
% apply to longer sequences (e.g., recency effects) and the
% FastLowBandwidth model does not take those factors into
% account.

% Return values are as follows. Each is a continuous time-history of
% model predictions, one per second, starting at 1-second. The values
% from seconds 1 through 4 aren't worth much, since it is questionable
% (perceptually speaking) to rate the quality of a very short video
% sequence. If you want a single prediction for an entire short video
% sequence (e.g., 5 to 30 seconds), then use the last value in each of
% these arrays and discard the prior values.
% 'vqm' is the FastLowBandwidth model's video quality prediction.
% The other return values ('hv_loss_par', 'hv_gain_par', 'si_loss_par',
% 'si_gain_par', 'color_comb_par', 'noise_par', and 'error_par')
% are the seven parameters. The model weights are applied to the
% parameters already, so that you can sum up these values to get 'vqm'.
% Thus, the weighted parameter values indicate the perceptual impact of
% each parameter on the viewer (e.g., how much of the quality drop was
% due to that factor).

%     ati_orig, part_ati_min, part_ati_max, part_ati, code_ati ] = ...
% model_lowbw_compression('uncompress', transmit_file);
% DESCRIPTION
% When the first argument is 'compress', this function compresses the
% features associated with the lowbw model or fastlowbw model, and write
% them to a file for transmission. Operates on 255 seconds or less. Longer
% sequences must be split and written to two different files. To
% understand the input arguments, see function model_lowbw_features or
% model_fastlowbw_features.
%
% When the first argument is 'uncompress', this function reverses the
% process: reads compressed original features from file 'transmit_file'
% and returns those values on the command line. This function also
% returns information about the feature compression, which will be needed
% by function model_lowbw_parameters.m and model_fastlowbw_parameters.m
% To properly understand those parameters (i.e., everything returned that
% isn't mentioned in the 'compress' argument list), examine the code

C.5.35 Function "quantiz_fast.m"

```

function y = quantiz_fast(x,t)
% QUANTIZ_FAST
% This function quantizes data. It is used as an alternative to the
% MATLAB routine, because at the time of writing it ran significantly
% faster.
% SYNTAX
% y = quantiz_fast(x,t)
% DESCRIPTION
% 'x' is the data to be quantized into discreet bins.

```

```

% 't' is the array of quantization thresholds.
% Return variable 'y' contains the quantized data.
%
% This code performs n=2^b level quantization of the signal samples in the
% row vector x to produce y. y will have the same size as x. t is a
% length n-1 row or column vector of quantization thresholds.
% This code works for all b=1,2,3,....
% Quantization rules are:
%   x <= t(1)      gives y = 0
%   t(1) < x <= t(2)    gives y = 1
%   ...
%   t(i) < x <= t(i+1)  gives y = i
%   ...
%   t(n-1) < x          gives y = n-1

n = length(x);
y = zeros(1,n);           %output variable starts with all zeros
b = log2(length(t)+1);   %number of bits
for i = 1:b               %loop over bits, each pass determines one bit
    temp = find(t(y+(2^(b-i))) < x);
    %compare each sample of x with corresponding current threshold
    y(temp) = y(temp)+(2^(b-i));
    %where x is above current threshold, update y to reflect this.
    %This update is equivalent to setting the current bit under
    %consideration (b-i) to 1.
end

```

C.5.36 Function "read_bigyuv.m"

```

function [y,cb,cr] = read_bigyuv(file_name, varargin);
% READ_BIGYUV
%   Read images from bigyuv-file.
% SYNTAX
%   [y] = read_bigyuv(file_name);
%   [y,cb,cr] = read_bigyuv(...);
%   [...] = read_bigyuv(...,'PropertyName',PropertyValue,...);
% DESCRIPTION
%   Read in images from bigyuv file named 'file_name'.
%
%   The luminance plane is returned in 'Y'; the color planes are
%   returned in 'cb' and 'cr' upon request. The Cb and Cr color planes
%   will be upsampled by 2 horizontally.
%
%   The following optional properties may be requested:
%
%   'sroi',top,left,bottom,right,
%                   Spatial region of interest to be returned. By default,
%                   the entirety of each image is returned.
%                   Inclusive coordinates (top,left),(bottom,right) start
%                   numbering with row/line number 1.
%   'size',row,col,    Size of images (row,col). By default, row=486,
%                   col=720.
%   'frames',start,stop,   Specify the first and last frames, inclusive,
%                   to be read ('start' and 'stop'). By
%                   default, the first frame is read.
%   '128'            Subtract 128 from all Cb and Cr values. By default, Cb
%                   and Cr values are left in the [0..255] range.
%   'interp'         Interpolate Cb and Cr values. By default, color
%                   planes are pixel replicated. Note: Interpolation is
%                   slow.
%
%   Color image pixels will be pixel replicated, so that Cb and Cr images

C.5.38 Function "running_collapse.m"

```

function [data] = running_collapse (request, raw_data, delta, property);
% RUNNING_COLLAPSE
% Perform a "running" spatial-temporal collapse over a long sequence.
% SYNTAX
% [data] = running_collapse (request, raw_data, delta, property);
% DESCRIPTION
% Take a request & raw_data, as defined by function st_collapse.
% 'property' is one of st_collapse's optional properties. Instead of
% calling st_collapse directly, divide it into shorter arrays, where the
% last non-unit dimension is of length 'delta'. Return the "running"
% collapse in 'data'. The length of data will be identical to the last
% dimension of 'raw_data'. The leading values (1 to time-1) will use
% shorter time lengths.
%
% 'raw_data' must be either 1D or 3D. See also function st_collapse.m

[row,col,time] = size(raw_data);
if time == 1,
    % 1D
    if col ~= 1,

C.5.39 Function "split_into_fields.m"

```
function [one, two] = split_into_fields(y);
% SPLIT_INTO_FIELDS
%   Splits one frame into two fields.
% SYNTAX
%   [one two] = split_into_fields(y);
% DESCRIPTION
%   Split frame 'y' into field one ('one') and field two ('two'). Field two
%   contains the top line of the image; field one contains the second line
%   of the image. For NTSC, field one occurs before field two in time. For
%   PAL, the reverse is the case. Y can be a time-slice of frames.
%
%   If image 'y' contains an odd number of rows, then the last (bottom) row
%   will be eliminated. See also function 'join_into_frames'

[row, col, time] = size(y);
if mod(row,2),
    y = y(1:row-1,1:col,1:time);
    [row, col, time] = size(y);
end
y = reshape(y,2,row/2,col,time);
two = squeeze(y(1,:,:,:,:));
one = squeeze(y(2,:,:,:,:));
```

C.5.40 Function "st_collapse.m"

```
function [data] = st_collapse(request, raw_data, varargin)
% ST_COLLAPSE
%   Compute the requested spatial or temporal collapsing function.
% SYNTAX
%   [data] = st_collapse(request, raw_data)
%   [data] = st_collapse(...,'PropertyName',...);
% DESCRIPTION
%   Compute the requested spatial or temporal collapsing function on the
%   FIRST dimension of the array or matrix, 'raw_data', and return the
%   results in 'data'. The available percentile functions are:
%   'mean', 'std', 'rms', 'min', 'max', '10%', '25%', '50%', '90%',
%   'above90%', 'above95%', 'above99%', 'above90%tail', 'above95%tail',
%   'above98%tail', 'above99%tail',
%   'below5%', 'below10%', 'below1%', 'below1%tail', 'below2%tail',
%   'below5%tail', 'below10%tail'
%   'below25%', 'above75%', 'below2%', 'above98%', 'below50%tail'
%   'between25%50%'
%       [ The meanings of the above are as defined in "Video Quality
%           Measurement Techniques" NTIA Technical Report 02-392. ]
% and 'minkowski(P,R)'.
%   [ minkowski = mean(abs(raw_data).^P).^(1/R) ]
%   Where 'P' and 'R' are replaced with the actual values to be
%   used. For example, 'minkowski(1.8,2.8)' or 'minkowski(6,7)'
%
% The following optional parameters are also available. All of these
% options are mutually exclusive.
%
%   'MacroBlock', row, col, time,
%       Apply the requested function to macro blocks, of size
% (row,col,time).
%       If the region does not evenly divide, center spatially, and
%       abut with the end of the raw data temporally.
%   'OverlapMacroBlock', row, col, time,
```

```

% Apply the requested function to macro blocks, of size
% (row,col,time).
% Unlike option 'MacroBlock', blocks overlap rather than
% abutting. Thus, returned data will be smaller only by
% (row-1) rows, (col-1) columns and (time-1) in time.
% 'SlideMacroBlock', row, col, time,
% Apply the requested function to macro blocks, of size
% (row,col,time).
% Blocks will overlap in time and abut spatially.
% '3D', Apply the requested function simultaneously to all
% dimensions. Thus, convert all of the data into a 1D array and
% apply the collapsing function to that 1D array.
% '1D', Apply the requested function to only the first
% dimensions. For example, the variable 'raw_data' should be 2D
% (spatial,temporal) or 1D (temporal). This is the default
% behaviour.

%
%
% WARNING: Unless 'MacroBlock' or '3D' arguments are selected, the
% requested function will be applied to the first dimension only!
%

%   frames at a given frame rate.
% SYNTAX
%   [tslice_frames, over_sec] = tslice_conversion (tslice_sec, fps)
% DESCRIPTION
%
% [tslice_frames, over_sec] = tslice_conversion (tslice_sec, fps)
% Given the current frame rate in frames per second ('fps') and the length
% of the current time-slice in seconds ('tslice_sec'), compute the
% length of the current time-slice in frames ('tslice_frames'). Also return
how
% much the chosen block length exceeds the requested block length, in
% seconds ('over_sec').
%
% NOTE: if the specified tslice_sec is within (plus or minus) one
% thousandth of one millisecond of being exactly tslice_frames
% (e.g., over_sec <= 0.000001), then this function will assume the
% user intended that exact number of tslice_frames.
%
% NOTE: Any time-slice smaller than one frame will be implemented as
% one frame per time-slice.

% compute length of time-slice, in frames
tslice_frames = ceil(tslice_sec * fps);

% compute amount of seconds that above measurement exceeds that requested.
over_sec = tslice_frames - tslice_sec * fps;

% if within 1 ms of an integer tslice_frames with over_sec = 0, use that.
if tslice_frames == 1,
    over_sec = 0;

```

```
elseif over_sec <= 0.000001,
    over_sec = 0;
elseif over_sec >= 0.999999,
    tslice_frames = tslice_frames - 1;
    over_sec = 0;
end
```

Appendix I

Transmission error analyses for the RRNR-TV validation tests

(This appendix does not form an integral part of this Recommendation)

NOTE – The analysis in this appendix is included for informative purposes only. The VQEG validation experiments were not initially designed to conduct this kind of analysis.

The VQEG validation tests for the RRNR-TV project included the 525-line (NTSC) and 625-line (PAL) formats. Each experiment included 12 source sequences and 156 processed video sequences (PVSs). Of these 156 PVSs, 40 contained transmission errors and 116 contained coding errors only. Tables I.1 and I.2 show the RMSE and OR for the PVSs with transmission errors. It is noted that the RMSE and OR were computed using the regression lines which were obtained from the entire data. In other words, the regression lines were computed using the entire data. Then, the RMSE and OR for transmission errors were computed using the PVSs with transmission errors.

Table I.1 – RMSE and OR for the RRNR-TV validation test (525-line format)

525-line format	ALL		With transmission errors		No transmission errors	
	RMSE	OR	RMSE	OR	RMSE	OR
Model_B 80k	0.598	0.667	0.768	0.650	0.544	0.586
