## FOREWORD

The ITU Telecommunication Standardization Sector (ITU-T) is a permanent organ of the International Telecommunication Union. The ITU-T is responsible for studying technical, operating and tariff questions and issuing Recommendations on them with a view to standardizing telecommunications on a worldwide basis.

The World Telecommunication Standardization Conference (WTSC), which meets every four years, established the topics for study by the ITU-T Study Groups which, in their turn, produce Recommendations on these topics.

ITU-T Recommendation Q.1211 was prepared by the ITU-T Study Group XI (1988-1993) and was approved by the WTSC (Helsinki, March 1-12, 1993).

---

## NOTES

1 As a consequence of a reform process within the International Telecommunication Union (ITU), the CCITT ceased to exist as of 28 February 1993. In its place, the ITU Telecommunication Standardization Sector (ITU-T) was created as of 1 March 1993. Similarly, in this reform process, the CCIR and the IFRB have been replaced by the Radiocommunication Sector.

In order not to delay publication of this Recommendation, no change has been made in the text to references containing the acronyms "CCITT, CCIR or IFRB" or their associated entities such as Plenary Assembly, Secretariat, etc. Future editions of this Recommendation will contain the proper terminology related to the new ITU structure.

2 In this Recommendation, the expression "Administration" is used for conciseness to indicate both a telecommunication administration and a recognized operating agency.

## **SUMMARY**

Intelligent network capability set 1 is the first standardized stage of the intelligent network (IN) as an architectural concept for the creation and provision of telecommunications services. This Recommendation gives an introduction to capability set 1 (CS-1) by providing an overview and definition of CS-1 and by describing its main characteristics and overall capabilities. It defines the service aspects, network aspects and functional relationships that form the basis of the CS-1 capabilities.

This Recommendation is the first in the Q.121x-Series Recommendations devoted to CS-1. It builds on the architectural principles of IN as described in the Q.120x-Series Recommendations.

The CS-1 Recommendations (Q.121x-Series) form a useful basis for achieving implementation experience. As with any project of this size and complexity, it can be anticipated that there may be some difficulties in interworking the various implementations of IN CS-1 physical elements. In order that the IN objective for working in a multi-vendor environment may be fully achieved, the IN CS-1 Recommendations text may go through some future revision in the light of implementation experience.

# **INTRODUCTION TO INTELLIGENT NETWORK CAPABILITY SET 1**

*(Helsinki, 1993)*

## **1 Introduction**

Intelligent network capability set 1 is the first standardized stage of the intelligent network (IN) as an architectural concept for the creation and provision of telecommunications services. This Recommendation gives an introduction to capability set 1 (CS-1) by providing an overview and definition of CS-1 and by describing its main characteristics and overall capabilities.

## **2 Phased standardization**

The intelligent network (IN) is an architectural concept for creation and provisioning of new services which is characterized by:

- a) extensive use of information processing techniques;
- b) efficient use of network resources;
- c) modularization and reusability of network functions;
- d) integrated service creation and implementation by means of modularized, reusable network functions;
- e) flexible allocation of network functions to physical entities;
- f) portability of network functions among physical entities;
- g) standardized communications between network functions via service independent interfaces;
- h) service subscriber's control of some subscriber-specific service attributes;
- i) service user control of some user-specific attributes;
- j) standardized management of service logic.

The implementation of the IN architecture will facilitate the rapid introduction of new services. Its architecture can be applied to various types of telecommunications networks, which include: public switched telecommunications network (PSTN), public switched packet data network (PSPDN), mobile, and integrated services digital networks (N- and B-ISDN).

The ultimate IN is an evolving target, therefore in order to take full advantage of the technological possibilities at a given point in time it is necessary to define specific phases in the evolution to a target architecture. This phased approach is shown in Figure 1.

This Recommendation provides the description of CS-1 at time  $T_1$  as represented in Figure 1.

## **3 General description and scope of CS-1**

### **3.1 Criteria for CS-1**

CS-1 defines an initial subset of IN capabilities that meet the following general criteria:

- a) CS-1 is a subset of the target intelligent network architecture;
- b) CS-1 is a set of definitions of capabilities that is of direct use to both manufacturers and network operators;

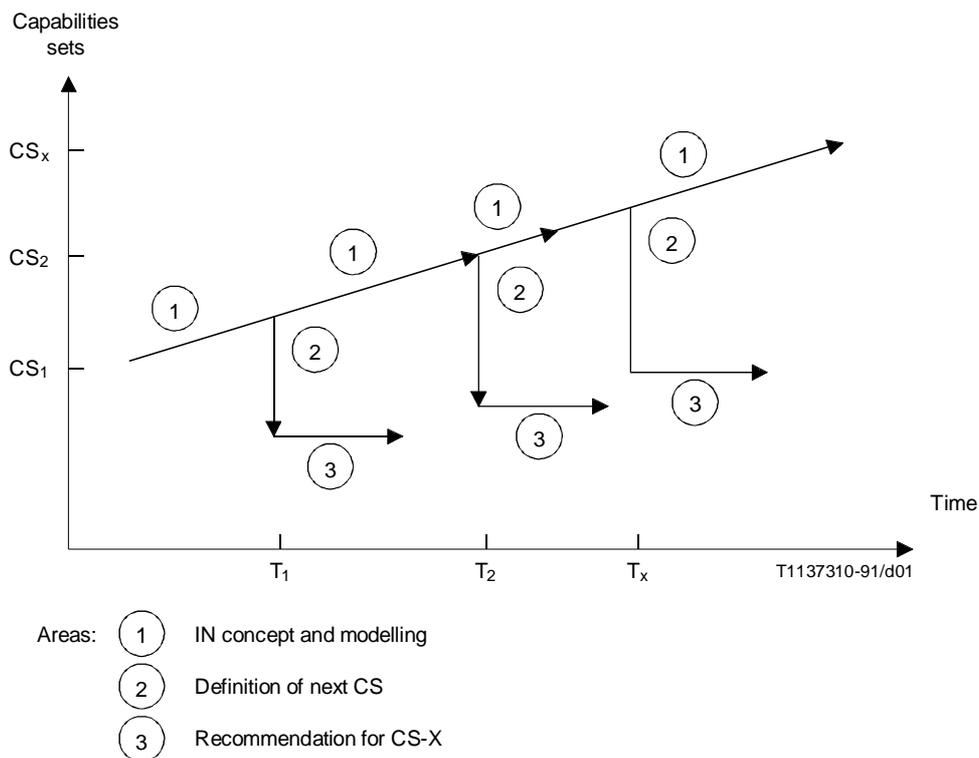

FIGURE 1/Q.1211  
Sequencing of capability sets

- c) CS-1 provides network capabilities to support services either defined or in the process of being defined by CCITT (e.g. universal personal telecommunications service, freephone, and virtual private network services such as private numbering plan). CS-1 also provides capabilities to support the introduction of services which may neither be standardized by CCITT, nor be part of the proposed set of targeted services;
- d) CS-1 is the first standardized stage of evolution based upon the existing technology base and on evolvability requirements addressed in 3.2.

The CS-1 architecture may be supported over PSTN, ISDN, and mobile networks.

### 3.2 Evolution of CS-1

The CS-1 Recommendations (Q.121x-Series) form a useful basis for achieving implementation experience. As with any project of this size and complexity, it can be anticipated that there may be some difficulties in interworking the various implementations of IN CS-1 physical elements. In order that the IN objective for working in a multi-vendor environment may be fully achieved, the IN CS-1 Recommendations text may go through some future revision in the light of implementation experience.

The CS-1 architecture takes into account the evolution requirement, i.e., it supports the CS-1 targeted services but its functionalities are designed to evolve towards the future capability sets (CS-2 and beyond). Therefore, the CS-1 capabilities are defined without any assumptions that are known to limit their ability to evolve into future capability sets.

## 4 Overview of CS-1 Recommendations

Table 1 contains an overview of the Recommendations that are specifically related to CS-1:

TABLE 1/Q.1211

### CS-1 Recommendations

Recommendation	Title
Q.1211	Introduction to intelligent network capability set 1
Q.1213	Global functional plane for intelligent network CS-1
Q.1214	Distributed functional plane for intelligent network CS-1
Q.1215	Physical plane for intelligent network CS-1
Q.1218	Intelligent network interface specifications for capability set 1
Q.1219	Intelligent network users guide for capability set 1

## 5 Service aspects

Although, by nature, the IN is a service independent architecture, it is relevant to describe the general CS-1 service capabilities. The services and service features that are to be supported by CS-1 are fundamental to the CS-1 service independent building blocks (SIBs), call processing model and service control principles.

### 5.1 Type A and Type B services

CS-1 capabilities are intended to support services and service features that fall into the category of “single ended”, “single point of control” services referred to as Type A, while all other services are placed in a category called Type B. The following definitions apply:

A single-ended service feature applies to one and only one party in a call and is orthogonal (independent) at both the service and topology levels to any other parties that may be participating in the call. Orthogonality allows another instance of the same or a different single-ended service feature to apply to another party in the same call as long as the service feature instances do not have feature interaction problems with each other.

Single point of control describes a control relationship where the same aspects of a call are influenced by one and only one service control function at any point in time (see also 6.2.1).

CS-1 standards do not encompass “Type B” services for the following reasons:

a) *Operational complexity*

In Type B services, several IN subscribers may be associated within a single call. During the call, subscribers may be added or dropped. These associations take place physically in the switches involved in the call (SSF/CCF functions) under the control of an SCF. The SCF will need rules to handle feature arbitration between subscribers involved in the call (e.g. incompatible screening lists). This may have to involve real-time consultations between the SCFs that “represent” the various parties involved in the call. Rules will also be required to handle topological decisions (e.g. which physical switches should be chosen to “join” groups of subscribers scattered around a network?).

b) *Implementation complexity*

Type B services may involve manipulation of switch connection resources by service logic located in an SCF. This means that an “abstracted” view of the switch’s connection resources must be made available to external service logic. Models have been formulated to accommodate appropriate “abstracted” views, but to date these are theoretical proposals. A very large investment in switch software redesign may be required to realize such models. In contrast, the switch software modifications to accommodate Type A services are relatively modest in scope and are well understood.

c) *Control complexity*

Type A services are characterized by a relatively simple control relationship between SSF and SCF. The SSF is a “client” for service-related information provided by the SCF, however, the switch retains connection control at all times.

In contrast, the control relationship between SCF and SSF in Type B services may require the sharing of connection control between the switch and external service logic. The information flows need to be rich in parameters to manage what is essentially a peer-peer, distributed processing relationship.

As there are considerable differences in operational, implementation, and control complexity between Type A and Type B services, CS-1 is targeted to support Type A services only.

There are some circumstances in which it will be possible to apply “Type A” IN technology to certain aspects of “Type B” services. This applies to switch-based services in general, whether these services be of “Type A” or “Type B”, and to “Type B” services in general, whether these be switch-based or CS-x based. Further detail can be obtained from Recommendation Q.1214.

## **5.2 Target sets of CS-1 services and service features**

Tables 2 and 3 contain the target sets of CS-1 services and service features. The target sets can be used to identify and verify the service-independent capabilities of CS-1. Examples of relationships and mappings between these CS-1 services and service features are shown in Annex A.

Annex B provides short prose descriptions of targeted services and service features. These were used to develop the current Q.121x-Series Recommendations as CS-1 is intended to support evolutionary new services. The descriptions provided for the targeted services and service features are for the above-mentioned purposes only and are not to be used by service designers for service creation.

Definitions of “service” and “service feature”:

A service is a stand-alone commercial offering, characterized by one or more core service features, and can be optionally enhanced by other service features.

A service feature is a specific aspect of a service that can also be used in conjunction with other services/service features as part of a commercial offering. It is either a core part of a service or an optional part offered as an enhancement to a service.

## **5.3 Network support of CS-1 services**

The services are to be supported over various networks. For IN CS-1 applications the following networks are considered:

- i) PSTN;
- ii) ISDN (Public and private networks);
- iii) PLMN.

TABLE 2/Q.1211

**Target set of CS-1 services**

Abbreviated dialling	ABD
Account card calling	ACC
Automatic alternative billing	AAB
Call distribution	CD
Call forwarding	CF
Call rerouting distribution	CRD
Completion of call to busy subscriber <sup>a)</sup>	CCBS
Conference calling <sup>a)</sup>	CON
Credit card calling	CCC
Destination call routing	DCR
Follow-me diversion	FMD
Freephone	FPH
Malicious call identification	MCI
Mass calling	MAS
Originating call screening	OCS
Premium rate	PRM
Security screening	SEC
Selective call forward on busy/don't answer	SCF
Split charging	SPL
Televoting	VOT
Terminating call screening	TCS
Universal access number	UAN
Universal personal telecommunications	UPT
User-defined routing	UDR
Virtual private network	VPN
<p>a) These services and service features might be partially supported in CS-1, because they require, beyond Type A capabilities, additional Type B capabilities. Parts of these service and service features are considered in CS-1 as long as these parts belong to Type A and do not impose capabilities additional to those required for other services and service features in the list.</p> <p>NOTES</p> <p>1 Above service names apply to the descriptions of targeted services (see Annex B), and not to the user-network interface descriptions provided by CCITT SG I.</p> <p>2 Network implementation aspects may be important for some services.</p>	

## 6 Network aspects

This clause provides an overview of the IN network functions, and sets guidelines for the control architecture of CS-1. It also describes how the issues of feature interaction and service-feature consistency are handled in CS-1.

Figure 2 summarizes the IN network functions and their functional relationships.

### 6.1 Network functions

The network functions are described here.

#### 6.1.1 Call control related functions

SSF – service switching function – this function interfaces with CCF and SCF. It allows the CCF to be directed by the SCF.

SRF – specialized resources function – this function provides a category of resources for access by other network entities. Examples of resources include DTMF sending and receiving, protocol conversion, speech recognition, synthesized speech provision, etc.

CCF – call control function – this function refers to call and connection handling in the classical sense (e.g., that of an exchange).

CCAF – call control agent function – this function provides the user access to the network.

TABLE 3/Q.1211

**Target set of CS-1 service features**

Abbreviated dialling	ABD
Attendant	ATT
Authentication	AUTC
Authorization code	AUTZ
Automatic call back <sup>a)</sup>	ACB
Call distribution	CD
Call forwarding	CF
Call forwarding on BY/DA	CFC
Call gapping	GAP
Call hold with announcement <sup>a)</sup>	CHA
Call limiter	LIM
Call logging	LOG
Call queueing	QUE
Call transfer <sup>a)</sup>	TRA
Call waiting <sup>a)</sup>	CW
Closed user group	CUG
Consultation calling <sup>a)</sup>	COC
Customer profile management	CPM
Customized recorded announcement	CRA
Customized ringing	CRG
Destinating user prompter	DUP
Follow-me diversion	FMD
Mass calling	MAS
Meet-me conference <sup>a)</sup>	MMC
Multi-way calling <sup>a)</sup>	MWC
Off net access	OFA
Off net calling	ONC
One number	ONE
Origin dependent routing	ODR
Originating call screening	OCS
Originating user prompter	OUP
Personal Numbering	PN
Premium charging	PRMC
Private numbering plan	PNP
Reverse charging	REVC
Split charging	SPLC
Terminating call screening	TCS
Time dependent routing	TDR

<sup>a)</sup> These services and service features might be partially supported in CS-1, because they require, beyond Type A capabilities, additional Type B capabilities. Parts of these service and service features are considered in CS-1 as long as these parts belong to Type A and do not impose capabilities additional to those required for other services and service features in the list.

NOTE – Above service feature names apply to the descriptions of targeted service features (see Annex B), and not to the user-network interface descriptions provided by CCITT SG I.

**6.1.2 Service control related functions**

SCF – service control function – this function contains the IN service logic and handles service-related processing activity.

SDF – service data function – this function handles access to service-related data and network data and provides consistency checks on data. It hides from the SCF the real data implementation and provides a logical data view to SCF.

**6.1.3 Management related functions**

SCEF – service creation environment function – this function allows an intelligent network service to be defined, developed, tested and input to the SMF. The output of this function involves service logic and service data templates.

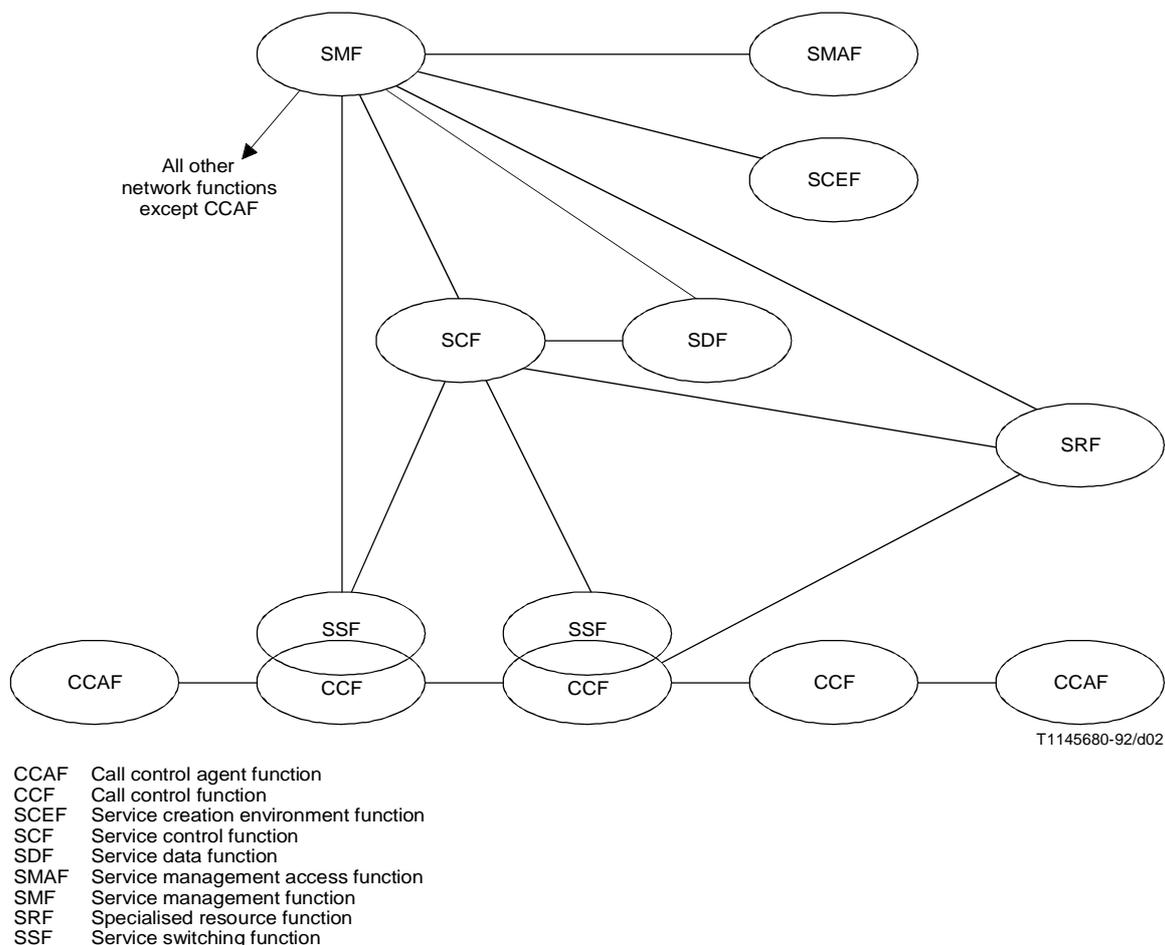

FIGURE 2/Q.1211  
**IN functions and functional relationships**

SMAF – service management access function – this function provides an interface (e.g. screen presentation, ...) to the SMF.

SMF – service management function – this function involves service management control, service provision control and service deployment control.

## 6.2 Control architecture principles

As stated in 5 (Service aspects), the service scope of CS-1 shall be restricted to single-ended, single-point-of-control services. This subclause identifies principles for the control architecture of CS-1, in the context of this service scope.

This subclause is organized around three control aspects:

- service invocation and control;
- end-user interaction with the SRF, and
- service management.

### **6.2.1 Service invocation and control**

This control aspect involves the CCF, SSF and SCF. It will be illustrated by considering an originating CS-1 call.

A CS-1 service request from a calling party will typically consist of an off-hook, and/or an appropriate sequence of dialled digits. The CCF has no CS-1 service “knowledge”, but is programmed to recognize that a CS-1 service request has taken place. It temporarily suspends call processing on behalf of the calling party, and passes appropriate call state information to the SSF.

The SSF is tightly coupled to the CCF, and in CS-1, it is expected that these two functions will constitute a single-vendor package. The role of the SSF is to interpret the service request and call state information, build a standardized query, and send the query via a standard protocol to the SCF.

SCF receives and decodes the query, and interprets it in the context of a CS-1 supported service. It formulates, encodes and sends a standardized response to the SSF. The formulation of the response may involve complex service logic leading to translations, the invocation of a prompt and collect sequence with the calling party (see also 6.2.2), or a query to a separate SDF.

The SSF receives, decodes and interprets the SCF’s response. It then provides explicit instructions to the CCF on how to complete the call set-up process on behalf of the end-user.

The following points capture key principles for CS-1:

- 1) The CCF retains ultimate responsibility for integrity of, and control of, the local connection at all times.
- 2) The SSF to SCF relationship is, by definition, service-independent. Therefore the CCF and SSF should never contain service logic specific to CS-1 supported services.
- 3) In the event of SCF malfunction, or time-out in the SCF to SSF response, the SSF/CCF combination should be capable of reverting to a default call completion sequence, with appropriate announcement(s) to the calling and/or called party.
- 4) The SSF should never have to interact with more than one SCF at any given time in order to complete a sequence of query/response interactions on behalf of a calling or called party. In other words, the SCF should be a “single point of contact” for the SSF at any given time.
- 5) Call hand-offs (transfer of responsibility) between SCFs, and between SSFs are permitted in CS-1. However, the hand-off must be explicit, and must not violate principle 4).

### **6.2.2 End-user (calling or called party) interaction with the SRF**

As part of the process of formulating a response to the SSF, the SCF may need to enter into a dialogue with the calling or called party. This would typically take the form of a prompt and collect sequence.

The SCF in CS-1 does not have the physical means to enter into this dialogue directly. Instead, it instructs the SRF to carry out a prompt and collect sequence with the calling or called party on its behalf.

In this typical scenario, the SCF would instruct the SSF to connect the end-user to an appropriate physical resource (e.g. a voice announcement system) within the SRF. It would also instruct the SRF on the particular prompt and collect sequence required. The SCF would then temporarily suspend processing of the call.

The SRF would activate the prompt and collect sequence, and enter into a dialogue with the calling or called party. The response (e.g. a personal identification number) would be encoded and returned to the SCF, and the voice connection to the SRF would be dropped. The SCF would then resume its service control sequence as outlined in 6.2.1.

The following points capture key principles for CS-1:

- 6) The SCF has full IN-supported service control of instruction formulation and sequencing with respect to the SRF and SSF.
- 7) As a corollary to principle 6), there shall be no direct service control interaction between the SSF and SRF for CS-1 based services. The SSF and SRF have a peer-peer relationship for the control of CS-1 based services, and both are subsidiary to the SCF.
- 8) The SCF will require the capability of suspending processing of a CS-1 based service on behalf of a calling or called party, and then resuming on behalf of the same party at a later time.

### **6.2.3 Service management**

The control aspects covered in 6.2.1 and 6.2.2 address the real-time interactions between CS-1 functions on behalf of a particular calling or called party. In contrast, the service management aspect primarily addresses the network operator's interaction with the SSF, SCF, SDF, and SRF. This interaction normally takes place outside the context of a particular call or service invocation.

However, CS-1 must neither exclude nor constrain the capability of service customers to interact directly with customer-specific service management information (e.g. a personal service profile).

The following points may be relevant to the CS-1 timeframe, but are not standardized in the CS-1 Recommendations:

- 9) The SMF, SCEF, and SMAF may be used to add, change or delete CS-1 based service related information or resources in the SSF, SCF, SDF, and SRF. Such changes should not interfere with CS-1 based service invocations or calls that are already in progress.
- 10) The network operator may, at its discretion, give the service customer the ability to add, change, or delete appropriate customer-specific information. The mechanisms and safeguards that are put into place by the network operator for this interaction may take advantage of CS-1 functions and capabilities.

## **6.3 Feature interactions**

The constraints placed on the CS-1 architecture have been put in place primarily to minimize and control feature interactions within single domains of responsibility.

The single-endedness of CS-1 based services means that all aspects of a call are under the control of one CCF/SSF and one SCF at any point in time [principle 4]. The SSF is therefore responsible for the handling of interactions between CS-1 based SSF/CCF capabilities, and non-IN features already embedded in CCF software.

The SSF/CCF functionality is expected to be implemented through a closely-coupled, single-vendor approach in CS-1. Therefore, this feature interaction problem will be constrained within single-vendor domains in CS-1, and will not require multi-vendor standards.

## **6.4 Consistency among CS-1 supported service features**

The ultimate responsibility for consistency of operations within a set of CS-1 based service features lies with the network operator. However, the software and data structures of the SCF, SDF, SMF and the tools provided by the SCEF, may be designed to aid the network operator in fulfilling this responsibility.

These are new areas for the telecommunications industry and CS-1 Recommendations should not seek to control or constrain market-driven implementations of SMF, SMAF, or SCEF.

## 7 Functional relationships and interfaces

### 7.1 Reference points and identifiers for functional relationships

Figure 3 identifies the 13 distinct functional relationships (presented in Figure 2) as reference points:

- A. CCAF-CCF;
- B. CCF-CCF;
- C. CCF-SRF;
- D. SSF-SCF;
- E. SCF-SRF;
- F. SCF-SDF;
- G. SMF-SCF;
- H. SMF-SDF;
- I. SMF-SRF;
- J. SMF-SMAF;
- K. SMF-SCEF;
- L. SMF-SSF/CCF; and
- M. SSF-CCF.

Five more functional relationships are related to network interworking, and they are introduced and discussed at the end of 7.

Only the D, E and F relationships are covered by the CS-1 Recommendations.

### 7.2 Control classes

The first six functional relationships of the above subclause (i.e., A, B, C, D, E, and F) require control capabilities. Four groupings of control capabilities, called control classes have been identified:

- 1) Connection-control capabilities – the capabilities to establish, provide surveillance, and clear the bearer connections (e.g., voice paths through the network).
- 2) Call-control (Non-IN Service-Control) capabilities – the capabilities to invoke the user and provide the end-to-end control required for the non-IN delivery of supplementary services. The non-IN delivery does not involve the structured separation of the CCF, SSF and SCF.
- 3) IN service-control capabilities – the capabilities that involve the structured separation of the SSF from SCF.
- 4) Management-related control capabilities.

The management-related control capabilities are not standardized in the CS-1 Recommendations.

### 7.3 Reference point identifiers and control relationships

The functional relationship at a reference point may provide for one or more control classes. Each combination of a functional relationship and a control class is referred to as a control relationship and is identified by an <alpha>.<numeric> string, where <alpha> identifies the functional relationship and <numeric> identifies the control class. For example, D.3 is the SSF-SCF control relationship for the IN service control.

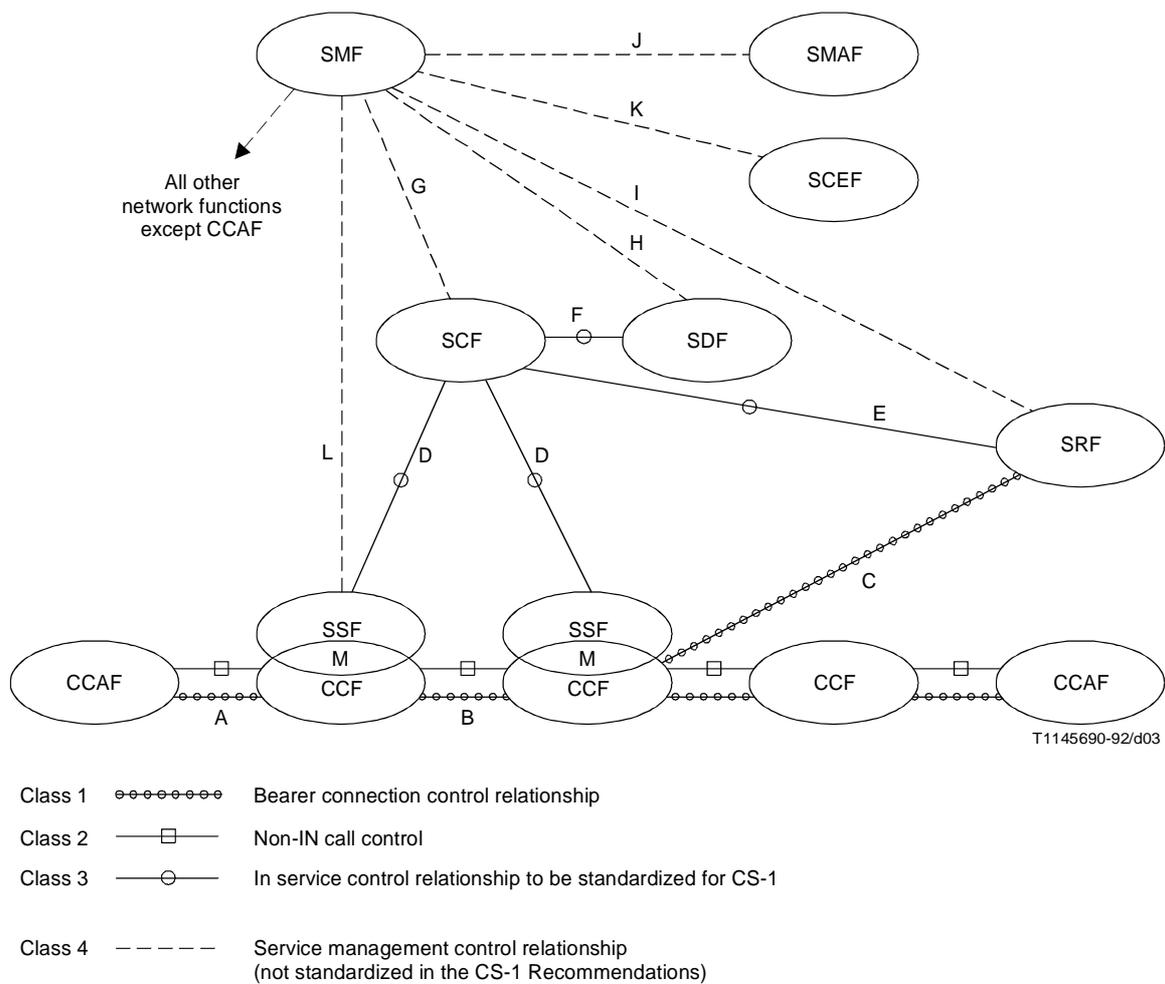

FIGURE 3/Q.1211  
**Functional relationships and reference points for CS-1**

#### 7.4 CS-1 non-IN connection and call control

For the CS-1 IN-structured network, the control relationships can be realized through existing standard interfaces as follows:

- A.1-DSS 1/Q.931;
- A.2-DSS 1/Q.932;
- B.1 and B.2-SS No. 7/ISUP; and
- C.1-DSS 1/Q.931; SS No. 7/ISUP.

The functional relationship at reference point M is, by its nature, non-standard. The CS-1 BCM/BCSM studies assure that the present digital switching technology can provide the SSF with a view into some of the basic call/connection capabilities of the CCF, which can be made available to the IN-supported service control offered by the SCF, consistent with the scope of CS-1.

## 7.5 CS-1 IN service control

CS-1 specifies three new functional relationships at reference points D, E, and F. The physical aspects of the realization of each functional relationship (e.g. the transport mechanism for carrying the control) do not imply a direct physical interface between the involved network functions. Indeed, the interconnection between two network functions may be provided through an SS No. 7 Network. In addition, for CS-1, the messages relevant to the reference point E may pass through a separate physical entity containing the SSF.

To this end, the CS-1 standardization defines the IN application service elements (ASEs) independent of the underlying protocol stack; the definition of ASEs aligns with ISO IS 9545.

The CS-1 IN standardization recommends that the IN ASEs be used with existing standardized protocol stacks. For the three new control relationships (at D, E and F), the existing standard protocol stacks include the following:

- D.3-SS No. 7/TCAP, DSS 1/Q.932;
- E.3-SS No. 7/TCAP, DSS 1/Q.932; and
- F.3-SS No. 7/TCAP, DSS 1/Q.932.

The ASEs at reference points D, E and F are defined separately within a common structure, helping to develop a modular and flexible IN application protocol (INAP). The INAP in turn, facilitates flexible packaging of the SSF, SCF, SDF and SRF into a variety of different physical entities.

While CS-1 supports a rich range of IN capabilities, its flexibility allows network operators to select only those that meet their individual service plans; a network operator may use only a subset of CS-1. For this reason, the CS-1 INAP supports the selection of different subsets of capabilities.

The number, nature, and content of the ASEs have been determined based on the decomposition of standardized SIBs. This process has also considered the services outlined in section 5.

As depicted in Figure 4, the definition of INAP ASEs reflects the capabilities that can be differentially applied to separate classes of services. These classes are as follows:

- Class 1 – The class that includes the services that benefit from IN service control in call set-up and tear-down phases.
- Class 2 – The class that includes the services that require mid-call control.
- Class 3 – The class that includes the services that require topology manipulation.

CS-1 can support a limited use of mid-call and topology manipulation capabilities, as noted in other Q.121x-Series Recommendations.

The substantial benefits from the standardized structural separation of SCF/SDF/SRF from SSF are as follows:

- this separation allows for the multi-vendor SSF and SCF implementations;
- this separation allows for the multi-vendor SRF implementations; and
- this separation allows for network interworking of the SCF and SDF implementations (e.g. the access of an SCF entity to an SDF entity in another network).

## 7.6 Service management for CS-1

The management-related functional relationships at reference points G, H, I, J, K and L remain to be specified in subsequent IN capability sets. For CS-1, it is expected that market forces will result in customer-responsive non-standard solutions for the associated interfaces, and that multi-vendor objectives of IN will be met in subsequent capability sets.

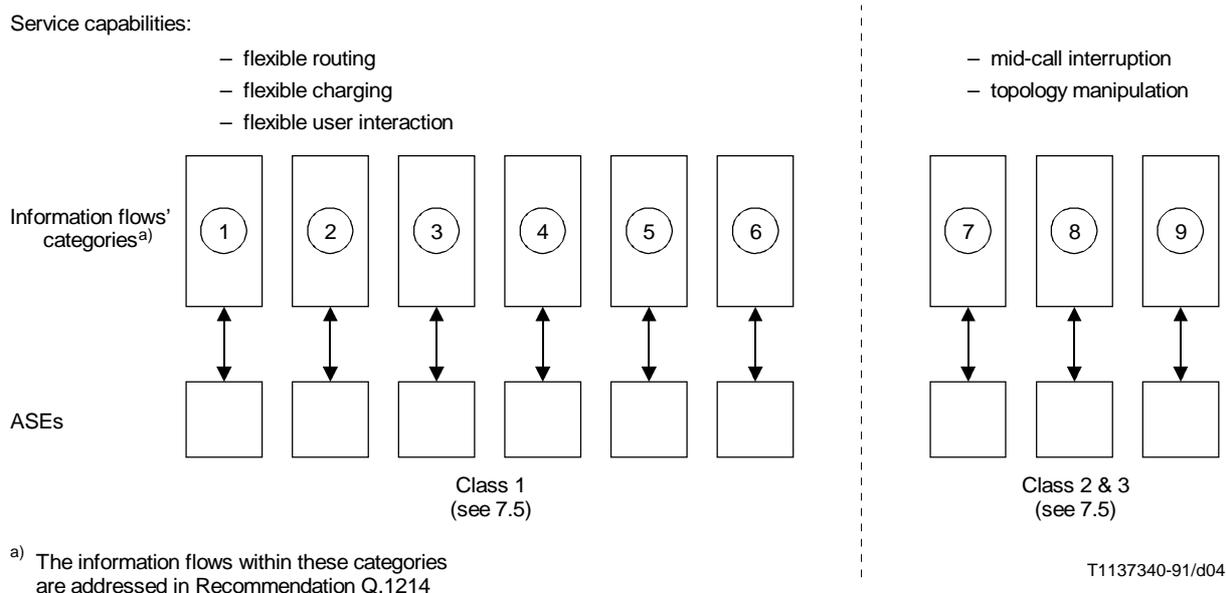

FIGURE 4/Q.1211  
**Categorization of information flows**

## 7.7 Network interworking in CS-1

Network interworking is a process in which several networks cooperate to provide a service. The need for interworking capabilities arises when customers wish to access the services that cannot be provided by one network alone. A typical example of such a situation is when the data needed by a service (e.g. UPT or VPN) reside in a network that is different from the one in which the call has originated.

General requirements for network interworking capabilities are presented in 2.2.6/Q.1201.

Although the involved networks may have different access types (i.e. PSTN, ISDN, etc.), as well as different levels of IN structure, the services should be provided to customers in a consistent way, regardless of such differences.

Similar to Figure 3, which depicts the functional relationships and their associated reference points between the IN functions within one network, Figure 5 depicts possible functional relationships between the IN functions that are located in two different networks:

- N. SSF-SCF;
- O. SCF-SCF;
- P. SCF-SDF;
- Q. SDF-SDF; and
- R. SMF-SMF.

As far as the CS-1 is concerned, the following observations can be made:

- 1) because it has been decided (cf. 2.2.6/Q.1201, which bases this decision on the necessity to maintain the network security and network integrity) interworking between the SSF in one network and the SCF in another one is not a CS-1 requirement, the functional relationship at reference point N is out of the scope of CS-1;

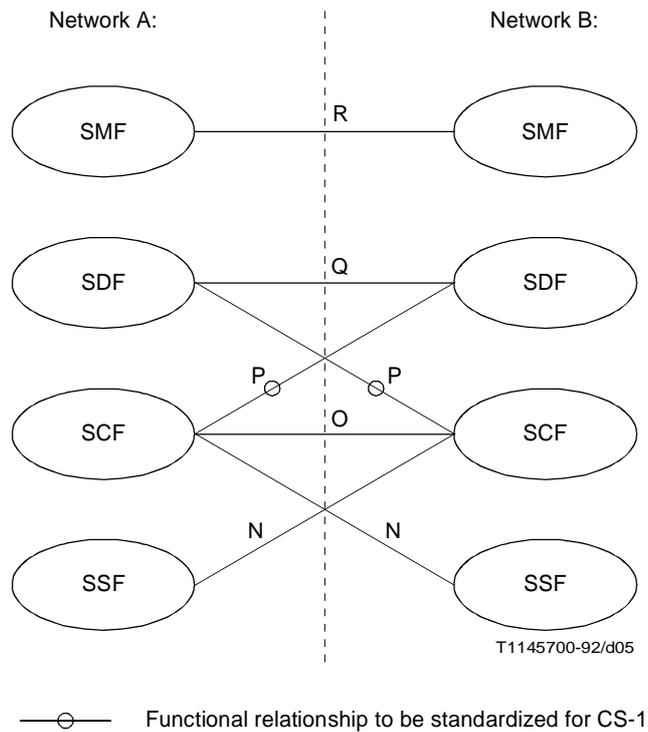

FIGURE 5/Q.1211

**Possible network interworking functional relationships**

- 2) because of the CS-1 requirement for a single point of control, there is no control relationship between two SCFs, and therefore the functional relationship at reference point O is out of the scope of CS-1;
- 3) because, for several IN supported services (e.g. UPT and VPN), the SCF performs translation and validation via information exchange with the SDF, the functional relationship at reference point P is within the scope of CS-1;
- 4) because the function of the SDF-to-SDF relationship is to hide the distributed nature of the IN data base from the SCF, it is not related to IN service control, and, therefore, the functional relationship at reference point Q is out of the scope of the CS-1 IN specification; and
- 5) because the SMF-to-SMF relationship is related to service management (i.e. TMN), the functional relationship at reference point R is out of the scope of the CS-1 IN specification.

The preceding analysis explains why the CS-1 IN network interworking effort has concentrated on developing information flows and relevant application layer protocol for the functional relationship at reference point P. Where possible, the CS-1 Recommendations Series identify the requirements for the services to be specified in other Recommendations (relative to the functional relationship at reference points Q and R). Wherever possible, the CS-1 Recommendations identify alternative interfaces (e.g. SCCP-GTT, X.500, or CMISE) for these domains.

## 7.8 Summary of CS-1 control relationships

Table 4 summarizes the CS-1 control relationships.

TABLE 4/Q.1211

Summary of CS-1 control relationships

CCAF										
CCF	A1,2	B1,2								
SSF		(M3)*								
SRF		C1								
SDF					(Q3)					
SCF			D3	E3	F3	P3	(O3)

UAN	O							C	O	O	O								O
UPT		O	C								O	C					C		O
UDR									O										O
VPN	O		O				O	O			O				C				O
C = Core		The particular service feature is fundamental to the service, i.e., in the absence of this service feature the name of the service does not make sense as a commercial offering to the service subscriber.																	
O = Optional		The service feature is not core, i.e., also without this service feature the name of the service would still make sense as a commercial offering to the service subscriber. Therefore, the service feature can be regarded an optional enhancement to the service.																	

## **Annex B**

### **Short prose descriptions of targeted services and service features**

(This annex forms an integral part of this Recommendation)

NOTE – The prose descriptions in this annex are only a compilation of available descriptions from various sources of targeted services and service features. These were used to develop the current Q.121x-Series Recommendations as CS-1 is intended to support evolutionary services. The descriptions provided for the targeted services and service features are for the above-mentioned purposes only and are not to be used by service designers for service creation.

There may be more than one prose description for each service/service feature. The descriptions are not necessarily consistent with each other.

#### **B.1 Descriptions of targeted services**

##### **B.1.1 Abbreviated dialling (ABD)**

This service is an originating line feature that allows business subscribers to dial others in their company using, e.g. only four digits even if the calling user's line and the called user's line are served by different switches. This capability extends switched based intercom calling beyond the switch boundary.

Typical scenarios might include:

- 1) Caller A (location A) dials extension number of caller B (location B) and the network connects the call.
- 2) Caller A forwards his line to called B (different location) using B's extension number. Caller C calls A and is forwarded to B.

##### **B.1.2 Account card calling (ACC)**

###### **B.1.2.1 Description No. 1**

The account card calling service allows a user to make a call from any card reading telephone and have the charges for the call automatically debited to a domestic or business account number as defined by the card content. The user is given an access code and a personal identification number (PIN). The user invokes the service by dialling the access code and on request, enters his PIN and "wipes" the card through the reader. The system validates the information and gives the user an indication of acceptance. The user can then proceed in the usual manner of making a call.

###### **B.1.2.2 Description No. 2**

The account card calling service allows subscribers to place calls from any normal access interface to any destination number and have the cost of those calls charged to the account specified by the ACC number.

###### **B.1.2.3 Description No. 3**

This service allows the caller to be automatically charged on a telephone account subscribed with the network operator, for any type of outgoing call. The caller has to dial his card number and a PIN, then the called number.

As an option, forward calls may be allowed, without dialling again card number and PIN.

##### **B.1.3 Automatic alternative billing (AAB)**

###### **B.1.3.1 Description No. 1**

The AAB service enables a user to make a call from any telephone and for the call charge to be billed to the user's account which is specific to this service, and which does not refer either to the calling line or to the called line.

An account code and PIN are allocated to a service user by service management procedure.

To invoke the service, the user dials an access code as a free call. Different access codes could be used to identify the language to be used. The user then receives announcements asking for him to dial his account code and PIN. The account code and PIN are validated, and a check could be made for expired credit limits.

NOTE – Account/credit card calling is similar, with the account No. being supplied using a card wipe.

#### **B.1.3.2 Description No. 2**

This service allows a user to call another user and ask him to receive the call at his expenses. Two steps may be defined: the calling party is welcomed to record a brief message giving the caller's name and explaining the call reason, then the called party is alerted, receives the recorded message and is asked to accept to be charged for that call.

#### **B.1.4 Call distribution (CD)**

This service allows a subscriber to have incoming calls routed to different destinations, according to an allocation law which may be real-time managed by the subscriber.

Three types of law may exist:

- circular distribution, where the calls are routed to the different locations with a uniform load;
- percentage distribution, where the calls are routed to the different locations according to a percentage;
- hierarchical distribution, where the first location to be chosen is the first met in the priority list.

In addition, congestion at one location may cause overflow calls to be rerouted to an alternate location.

#### **B.1.5 Call forwarding (CF)**

##### **B.1.5.1 Description No. 1**

Call forwarding allows the called user to forward calls to another telephone number when this service is activated. With this service, all calls destined to the subscriber's number are redirected to the new telephone number.

This service is under control of the subscriber and can be activated/deactivated by the subscriber.

When this service is activated, the subscriber's line will receive an alerting ring, "reminder ring", to indicate that the service is activated.

##### **B.1.5.2 Description No. 2**

This service permits the user to have his incoming calls addressed to another number, no matter what the called party line status is. The user's originating service is unaffected, even for charging.

#### **B.1.6 Call rerouting distribution (CRD)**

This service permits the subscriber to have his incoming calls encountering a triggering condition (busy, specified number or rings, queue overload or call limiter) rerouted according to a predefined choice: the calls may be rerouted to another destination number (including pager or vocal box), rerouted on a standard or customized announcement, or queued.

#### **B.1.7 Completion of calls to busy subscriber (CCBS)**

This service allows a calling user encountering a busy destination to be informed when the busy destination becomes free, without having to make a new call attempt.

### **B.1.8 Conference calling (CON)**

Conference calling allows the connection of multiple parties in a single conversation. The number of parties allowed to be connected simultaneously will vary based on transmission bridging requirements to ensure Quality of Service.

#### **B.1.8.1 Conference calling add-on**

This service allows the user to reserve a conference resource for making a multi-party call, indicating the date, time and conference duration. Once the conference is active, the user controls the conference, and may add, drop, isolate, reattach or split parties.

#### **B.1.8.2 Conference calling meet-me**

This service allows the user to reserve a conference resource for making a multi-party call, indicating the date, time and conference duration. In due time, each participant in the conference has to dial a special number which has been attached to the booked conference, in order to access to the conference bridge.

### **B.1.9 Credit card calling (CCC)**

#### **B.1.9.1 Description No. 1**

The credit card calling service allows subscribers to place calls from any normal access interface to any destination number and have the cost of those calls charged to the account specified by the CCC number.

#### **B.1.9.2 Description No. 2**

This service allows the caller to be automatically charged on a bank card account, for any type of outgoing call. The caller has to dial his card number and a PIN, then the called number.

As an option, forward calls may be allowed, without dialling again card number and PIN.

### **B.1.10 Destination call routing (DCR)**

#### **B.1.10.1 Description No. 1**

This service allows customers to specify the routing of their calls to destinations according to:

- a) time of day, day of week, etc.;
- b) area of call origination;
- c) calling line identity of customer;
- d) service attributes held against the customer;
- e) priority (e.g. from input of a PIN);
- f) charge rates applicable for the destinations;
- g) proportional routing of traffic.

#### **B.1.10.2 Description No. 2**

Destination call routing allows a subscriber to have incoming calls routed to different destinations, based upon the geographic locations of the calling parties. There are also optional reports which provide the subscriber with data on all their incoming calls and can include details such as date and time of call.

Typical call scenarios might include:

- 1) Calling user A dials subscriber's published directory numbers (DN) and, based upon geographic criteria, is routed to subscriber's location C.
- 2) Calling user B dials subscriber's published DN and, based upon geographic criteria, is routed to subscriber's location D.

## **B.1.11 Follow-me diversion (FMD)**

### **B.1.11.1 Description No. 1**

Follow-me diversion allows the service subscriber to remotely control the redirection (diversion) of calls from his primary telephone number to other locations. The subscriber is allowed to update the diversion location telephone number, from a standard telephone instrument, as he moves from location to location.

### **B.1.11.2 Description No. 2**

This service allows the subscriber to remotely control his call forwarding capabilities, basically the number to which the calls are forwarded, from any point in the network.

### **B.1.11.3 Description No. 3**

With this service, a user may register for incoming calls to any terminal access. When registered, all incoming calls to the user will be presented to this terminal access. A registration for incoming calls will cancel any previous registration. Several users may register for incoming calls to the same terminal access simultaneously. The user may also explicitly deregister for incoming calls.

## **B.1.12 Freephone (FPH)**

### **B.1.12.1 Description No. 1**

This service allows a reverse charging, the subscriber accepting to receive calls at his expenses and being charged for the whole cost of the call.

### **B.1.12.2 Description No. 2**

Freephone allows the served user having one or several installations to be reached from all or part of the country, or internationally as appropriate, with a freephone number and to be charged for this kind of call.

## **B.1.13 Malicious call identification (MCI)**

### **B.1.13.1 Description No. 1**

Malicious call identification allows the service subscriber to control the logging (making a record) of calls that are received that are of a malicious nature.

### **B.1.13.2 Description No. 2**

This service enables a user to request that the source of an incoming call is identified and registered in the network. The following information at least is to be registered: called party number, calling party number, time and date of the request. The service may be invoked either during or after the active phase of the call, but before the called user has cleared; as an option, it may be invoked by the network on all calls that are not answered.

As an option, the holding of the connection may be provided until the intervention of the service provider.

## **B.1.14 Mass calling (MAS)**

### **B.1.14.1 Description No. 1**

Using this service, the network operator can temporarily allocate a single directory number to the served user. Each time a call is made to this number by an end user, the user will be played an announcement and asked to input a further digit to indicate a preference. The choice made will be recorded and a count incremented. When the service has ceased, the network operator will supply details of the total "votes" cast for each preference will be supplied to the served user and the special number will be reallocated. Calls made to this special number may be charged at varying rates.

### **B.1.14.2 Description No. 2**

Mass calling involves instantaneous, high-volume traffic which is routed to one or multiple destination(s). Calls can be routed to these destination numbers based on various conditions, such as the geographical location or time of day. The calling party will be charged for this kind of call.

## **B.1.15 Originating call screening (OCS)**

### **B.1.15.1 Description No. 1**

Originating calls may be controlled by the originating call screening capability. This allows the subscriber to specify that outgoing calls be either restricted or allowed, according to a screening list and, optionally, by time of day control. This can be overridden on a per-call basis by anyone with the proper identity code.

Typical scenarios might include:

- 1) Calling user A attempts to make a call. The call is screened via the screening list assigned to the originating line. The call is allowed to complete and is connected.
- 2) Calling user A attempts to make a call to a line with deactivated override feature. The call is screened via the screening list assigned to the originating line. The call is not allowed to complete. Since the override option is not active, there are no override prompts.
- 3) Calling user A attempts to make a call to a line with an activated override feature. The call is screened via the screening list assigned to the originating line. The call is not allowed to complete. Since the override option is active, the user is prompted for the identity code and enters the proper code. The call is connected.

### **B.1.15.2 Description No. 2**

This service allows a subscriber to authorize outgoing calls, through the use of a screening list. This list may be managed by the subscriber. The user may override the restriction by giving a PIN.

## **B.1.16 Premium rate (PRM)**

### **B.1.16.1 Description No. 1**

This service allows to pay back a part of the call cost to the called party, considered as an added value service provider.

### **B.1.16.2 Description No. 2**

Premium rate allows the served user having one or several installations to be reached from all or part of the country, or internationally as appropriate, with a premium rate number. The calling party will be charged with a premium rate for this kind of call.

It is a service that can be available in the public telephone network whereby, a service provider having connections to the public network can be allocated a special telephone number by a network operator, known as a premium rate number.

The provider is able to earn revenue for each call successfully made to his premium rate number. In return he provides callers with some form of information service via the call connection. Calls to the premium rate number are charged to the caller at special rates to cover the price of the call and the price of the information service. The network operator Administration collects the revenue for each call and shares it with the provider.

The geographical location of the provider is unrelated to his premium rate number i.e., he can be located anywhere in the network. The provider may specify the catchment area from which he wishes to receive calls. In the case of multi-site providers, the site to which the caller is connected can depend on the catchment area in which the call originated.

## **B.1.17 Security screening (SEC)**

### **B.1.17.1 Description No. 1**

This capability allows security screening to be performed in the network before an end-user gains access to the subscriber's network, systems, or applications. Access code abuse detection is a capability which will generate a report on the invalid access attempts: how many, over what time period, by whom, and from where. This provides an added layer of security.

The following are typical call scenarios for these capabilities:

- 1) Caller A dials subscriber's DN, enters correct personal identification number (PIN) when prompted, clears network screening and is connected. Call data is recorded.
- 2) Caller B dials subscriber's DN, enters invalid PIN on first and subsequent prompts, fails network screening, and is connected to announcement. Call data is recorded and reports of invalid codes attempted are printed.
- 3) Caller C dials subscriber's DN, initially enters incorrect PIN, but corrects it upon re-prompt, clears network screening, and is connected. Call data is recorded along with re-prompts/re-entries.

#### **B.1.17.2 Description No. 2**

This service asks the user to dial a pin code, which allows the verification of the user identity before giving the user access to the subscriber's network, systems or application. As an option, the invalid access attempts may be registered.

#### **B.1.18 Selective call forwarding on busy/don't answer (SCF)**

##### **B.1.18.1 Description No. 1**

Selective call forwarding – busy/don't answer (SCF-BY/DA) allows the called user to forward particular pre-selected calls if the called user is busy or does not answer within Y seconds or X rings. The calls will be pre-selected based upon an SCF-BY/DA list. This list will have 1 to 5 or 1 to 10 numbers with a default call forward number for calling users not in the list. There will also be remote access and time of day indicators for this capability.

Typical scenarios may include:

- 1) Called user B has SCF-BY/DA assigned. Caller A dials B's number, called B does not answer the phone within Y seconds. Based upon the SCF-BY/DA list, caller A is forwarded to user C.
- 2) Called user B has SCF-BY/DA assigned. Caller D dials called B's number, called B is busy with called user C. Based upon the SCF-BY/DA list, caller D is forwarded to user E.
- 3) Called user B has SCF-BY/DA assigned. Caller A and caller C dial called B's number, called B does not answer the phone within Y seconds. Based upon the SCF-BY/DA list entry for caller A, caller A is forwarded to user D. Caller C is not in list, therefore caller C is forwarded to default user E.

#### **B.1.19 Selective call forwarding**

This service permits the user to have his incoming calls addressed to another number, no matter what the called party line status is, if the calling line identity is included in, or excluded from, a screening list. The user's originating service is unaffected, even for charging.

#### **B.1.20 Call forwarding on busy**

This service permits the user to have his incoming calls addressed to another number if they encounter a busy condition. The user's originating service is unaffected, even for charging.

#### **B.1.21 Call forwarding on don't answer (no reply)**

This service permits the user to have his incoming calls addressed to another number, if they encounter no reply. The user's originating service is unaffected, even for charging.

#### **B.1.22 Split charging (SPL)**

##### **B.1.22.1 Description No. 1**

This service allows a split charging, the calling and the called party being each charged for one part of the call.

### **B.1.22.2 Description No. 2**

This service enables a network operator to distribute the charges for a call between the two parties involved.

### **B.1.22.3 Description No. 3**

Split charging allows the service user having one or several installations to be reached from all or part of the country, or internationally as appropriate, with a split charging number. Both the calling party and the served user will be charged with a split charging rate for this kind of call.

## **B.1.23 Televoting (VOT)**

### **B.1.23.1 Description No. 1**

This service allows the subscriber to propose a phone voting, the user being asked either to ring a specific number according to his choice, or to ring a unique number and, after prompting, to give his choice by keyboard or by voice dialogue.

### **B.1.23.2 Description No. 2**

Televoting enables subscribers to survey public opinion using the telephone network. Persons wishing to respond to an opinion poll can call advertised televoting numbers to register their votes. The charging is to the discretion of the service subscriber.

### **B.1.23.3 Description No. 3**

Using this service, the network operator can temporarily allocate directory numbers to the served user. Each time a call is made to one of the numbers by an end user, the user will be played an announcement acknowledging the call, and a count of calls made to this number will be incremented. When televoting has ceased, the network operator will supply details of the total numbers of calls made to each number to the served user and the special numbers will be reallocated. Calls made to these special numbers may be charged at varying rates.

## **B.1.24 Terminating call screening (TCS)**

Terminating calls may be controlled by the terminating call screening capability. This allows the subscriber to specify that incoming calls be either restricted or allowed, according to a screening list and optionally, by time of day control.

Typical scenarios might include:

- 1) Calling user A attempts to make a call to B. The call is screened via the screening list assigned to B's line. The call is allowed to complete and is connected.
- 2) Calling user A attempts to make a call to B. The call is screened via the screening list to B's line. The call is not allowed to complete and is connected to an announcement.

## **B.1.25 Universal access number (UAN)**

### **B.1.25.1 Description No. 1**

This service allows a subscriber with several terminating lines in any number of locations or zones to be reached with a unique directory number. The subscriber may specify which incoming calls are to be routed to which terminating lines, based upon the area the call originated.

### **B.1.25.2 Description No. 2**

This service enables a service provider to publish a national number and have incoming calls routed to a number of different destinations based on the geographical location of the caller.

One typical scenario might have the published national number as a freephone number.

There should be an option to provide the service provider with subscriber data on all incoming calls such as date and time of call and the service provider's location that the call was routed to.

## **B.1.26 Universal personal telecommunications (UPT)**

### **B.1.26.1 Description No. 1**

UPT is a mobility service which enables subscribers to make use of telecommunication services on the basis of a unique personal telecommunication number (PTN) across multiple networks at any network access. The PTN will be translated to an appropriate destination number for routing based on the capabilities subscribed to by each service subscriber.

### **B.1.26.2 Description No. 2**

This service provides personal mobility by enabling a user to initiate any type of service and receive any type of call on the basis of a unique and personal network-independent number, across multiple networks, at any user-network access (fixed, movable or mobile), irrespective of geographic location, limited only by terminal and network capabilities.

## **B.1.27 User-defined routing (UDR)**

This capability allows the subscriber to specify how outgoing calls, from the subscriber's location, shall be routed, either through private, public, or virtual facilities or a mix of facilities, according to the subscriber's routing preference list. These lists will apply to individual lines or to several lines at the subscriber's location.

Typical scenarios might include:

- 1) Calling user A dials from the subscriber's line; the subscriber's routing list specifies the call will only be routed over private facilities.
- 2) Calling user A dials from the subscriber's line and the subscriber's routing list allows public facilities between 1600 and 0800 and private facilities from 0800 to 1600. Time is 1531, so call is routed only over private facilities to location. Calling User A now dials from subscriber's line at 1608 and so call is routed over public route to the destination.

## **B.1.28 Virtual private network (VPN)**

### **B.1.28.1 Description No. 1**

This service permits to build a private network by using the public network resources. The subscriber's lines, connected on different network switches, constitute a virtual PABX, including a number of PABX capabilities, such as private numbering plan (PNP), call transfer, call hold, and so on.

As an option, to each private user, either a class of service or specific rights and privileges may be attributed. As another option, a private user may access his private network from any point in the network keeping, after authentication, his class of service or his specific rights and privileges.

### **B.1.28.2 Description No. 2**

This service permits the use of public network resources to provide private network capabilities without necessarily using dedicated network resources. The subscriber's lines, connected to different network switches, constitutes a virtual private network that may include private network capabilities, such as dialling restrictions, private numbering plan, hold, call transfer, and so on.

A PNP may provide a group of users the capability to place calls by using digit sequences having different structures and meaning than provided by the public numbering plan, or PNP may utilize the public numbering plan's digit sequences, structures and meaning.

### **B.1.28.3 Description No. 3**

VPN allows a subscriber to define and use a private numbering plan for communication across one or more networks between nominated user access interfaces. A PNP provides a group of users the capability to place calls by using digit sequences having different structures and meanings than provided by the public numbering plan.

## **B.2 Descriptions of targeted service features**

### **B.2.1 Abbreviated dialling (ABD)**

#### **B.2.1.1 Description No. 1**

This feature allows the definition of abbreviated dialling numbers with a VPN. For the users of the VPN, the abbreviated dialling numbers are not subjected to call restrictions, e.g. a VPN user may not be allowed to access the Off-net Calling service feature but can reach an off-net number via this feature.

#### **B.2.1.2 Description No. 2**

This feature allows the definition of abbreviated dialling digit sequences to represent the actual dialling digit sequence, i.e., a two digit sequence may represent a complete dialling sequence for a private or public numbering plan.

#### **B.2.1.3 Description No. 3**

This service feature is an originating line feature that allows business subscribers to dial others in their company using a short numbering, even if the calling user's line and the called user's line are served by different switches.

### **B.2.2 Attendant (ATT)**

This service feature allows VPN users to access an attendant position within the VPN for providing VPN service information (e.g. VPN numbers). The attendant(s) can be accessed by dialling a special access code.

### **B.2.3 Authentication (AUTC)**

This service feature allows for the verification that a user is allowed to exercise certain options in a telephone network. In other words, the request made by the user is authentic and should be granted.

### **B.2.4 Authorization code (AUTZ)**

This service feature allows a VPN user to override calling restrictions of the VPN station from which the call is made. Different sets of calling privileges can be assigned to different authorization codes and a given authorization code can be shared by multiple users.

### **B.2.5 Automatic call back (ACB)**

This service feature allows the called party to automatically call back the calling party of the last call directed to the called party.

### **B.2.6 Call distribution (CD)**

This service feature allows the served user to specify the percentage of calls to be distributed among two or more destinations. Other criteria may also apply to the distribution of calls to each destination.

### **B.2.7 Call forwarding (CF)**

This service feature allows the user to have his incoming calls addressed to another number, no matter what the called party line status may be.

### **B.2.8 Call forwarding on busy/don't answer (CFC)**

This service feature allows the called user to forward particular calls if the called user is busy or does not answer within a specified number of rings.

## **B.2.9 Call gapping (GAP)**

### **B.2.9.1 Description No. 1**

This service feature allows the service provider to automatically restrict the number of calls to be routed to the subscriber.

### **B.2.9.2 Description No. 2**

This service feature allows to restrict the number of calls to a served user to prevent congestion of the network.

## **B.2.10 Call hold with announcement (CHA)**

The call hold with announcement service feature allows a subscriber to place a call on hold with options to play music or customized announcements to the held party.

## **B.2.11 Call limiter (LIM)**

### **B.2.11.1 Description No. 1**

This service feature allows a served user to specify the maximum number of simultaneous calls to a served user's destination. If the destination is busy, the call may be routed to an alternative destination.

### **B.2.11.2 Description No. 2**

This service feature enables to count the running calls to the subscriber and to reject all the new calls when a threshold of simultaneous calls is reached. As an option, this threshold may be real-time managed by the subscriber.

Associated with call volume distribution or call distribution, it allows the rerouting of the new calls.

## **B.2.12 Call logging (LOG)**

This service feature allows for a record to be prepared each time that a call is received to a specified telephone number.

## **B.2.13 Call queueing (QUE)**

### **B.2.13.1 Description No. 1**

This service feature allows a served user to have calls meeting busy at the scheduled destination to be placed in a queue and connected as soon as free condition is detected. Upon entering the queue, the caller hears an initial announcement informing the caller that the call will be answered when a line is available.

### **B.2.13.2 Description No. 2**

This service feature enables the subscriber, when a call encounters a terminating trigger such as a busy condition or a specified number of rings to queue that call, a specific announcement being sent to the calling party.

## **B.2.14 Call transfer (TRA)**

The call transfer service feature allows a subscriber to place a call on hold and transfer the call to another location.

## **B.2.15 Call waiting (CW)**

This service feature allows the called party to receive a notification that another party is trying to reach his number while he is busy talking to another calling party.

### **B.2.16 Closed user group (CUG)**

This service feature allows the user to be a member of a set of VPN users who are normally authorized to make and/or receive calls only within the group. A user can belong to more than one CUG. In this way, a CUG can be defined so that certain users are allowed either to make calls outside the CUG, or to receive calls from outside the CUG, or both.

### **B.2.17 Consultation calling (COC)**

The consultation calling service feature allows a subscriber to place a call on hold, in order to initiate a new call for consultation.

### **B.2.18 Customer profile management (CPM)**

This service feature allows the subscriber to real-time manage his service profile, i.e., terminating destinations, announcements to be played, call distribution, and so on.

### **B.2.19 Customized recorded announcement (CRA)**

This service feature allows a call to be completed to a (customized) terminating announcement instead of a subscriber line. The served user may define different announcements for unsuccessful call completions due to different reasons (e.g. caller outside business hours, all lines are busy).

### **B.2.20 Customized ringing (CRG)**

This service feature allows the subscriber to allocate a distinctive ringing to a list of calling parties.

### **B.2.21 Destinating user prompter (DUP)**

This service feature enables to prompt the called party with a specific announcement. Such an announcement may ask the called party to enter an extra numbering, e.g. through dual-tone multi-frequency (DTMF), or a voice instruction that can be used by the service logic to continue to process the call.

### **B.2.22 Follow-me diversion (FMD)**

#### **B.2.22.1 Description No. 1**

This service feature allows a VPN user to change the routing number of his/her VPN code via a DTMF phone. The updated number can be another VPN code or a PSTN number.

#### **B.2.22.2 Description No. 2**

With this service feature, a user may register for incoming calls to any terminal access. When registered, all incoming calls to the user will be presented to this terminal access. A registration for incoming calls will cancel any previous registration. Several users may register for incoming calls to the same terminal access simultaneously. The user may also explicitly deregister for incoming calls.

### **B.2.23 Mass calling (MAS)**

This service feature allows processing of huge numbers of incoming calls, generated by broadcasted advertisements or games.

### **B.2.24 Meet-me conference (MMC)**

This service feature allows the user to reserve a conference resource for making a multi-party call, indicating the date, time, and conference duration. At the specified date and time, each participant in the conference has to dial a designated number which has been assigned to the reserved conference resource, in order to have access to that resource, and therefore, the conference.

### **B.2.25 Multiway calling (MWC)**

This service feature allows the user to establish multiple, simultaneous telephone calls with other parties.

### **B.2.26 Off-net access (OFA)**

This service feature allows a VPN user to access his or her VPN from any non-VPN station in the PSTN by using a personal identification number (PIN). Different sets of calling privileges can be assigned to different PINs, and a given PIN can be shared by multiple users.

### **B.2.27 Off-net calling (ONC)**

This service feature allows the user to call outside the VPN network. Calls from one VPN to another are also considered off-net.

### **B.2.28 One number (ONE)**

This feature allows a subscriber with two or more terminating lines in any number of locations to have a single telephone number. This allows businesses to advertise just one telephone number throughout their market area and to maintain their operations in different locations to maximize efficiency. The subscriber can specify which calls are to be terminated on which terminating lines based on the area the calls originate.

### **B.2.29 Origin dependent routing (ODR)**

This service feature enables the subscriber to accept or reject a call, and in case of acceptance, to route this call, according to the calling party geographical location. This service feature allows the served user to specify the destination installation(s) according to the geographical area from which the call was originated.

### **B.2.30 Originating call screening (OCS)**

This service feature allows the served user to bar calls from certain areas based on the District code of the area from which the call is originated.

### **B.2.31 Originating user prompter (OUP)**

#### **B.2.31.1 Description No. 1**

This service feature allows a served user to provide an announcement which will request the caller to enter a digit or series of digits via a dual-tone multi-frequency (DTMF) phone or generator. The collected digits will provide additional information that can be used for direct routing or as a security check during call processing.

#### **B.2.31.2 Description No. 2**

This service feature enables to prompt the calling party with a specific announcement. Such an announcement may ask the calling party to enter an extra numbering (e.g. through DTMF) or a voice instruction that can be used by the service logic to continue to process the call.

### **B.2.32 Personal numbering (PN)**

This service feature supports a UPT number that uniquely identifies each UPT user and is used by the caller to reach that UPT user. A UPT user may have more than one UPT number for different applications (e.g. a business UPT number for business calls and a private UPT number for private calls), however, a UPT user will have only one UPT number per charging account.

### **B.2.33 Premium charging (PRMC)**

This service feature allows for the pay back of the part of the cost of a call to the called party, when he is considered as a value added service provider.

#### **B.2.34 Private numbering plan (PNP)**

This service feature allows the subscriber to maintain a numbering plan within his private network, which is separate from the public numbering plan.

NOTE – See also definition under VPN description.

#### **B.2.35 Reverse charging (REVC)**

This service feature allows the service subscriber (e.g. freephone) to accept to receive calls at its expense and be charged for the entire cost of the call.

#### **B.2.36 Split charging (SPLC)**

This service feature allows for the separation of charges for a specific call, the calling and called party each being charged for one part of the call.

#### **B.2.37 Terminating call screening (TCS)**

This service feature allows the user to screen calls based on the terminating telephone number dialled.

#### **B.2.38 Time dependent routing (TDR)**

##### **B.2.38.1 Description No. 1**

This service feature enables the subscriber to accept or reject a call, and in case of acceptance, to route this call, according to the time, the day in the week and the date.

##### **B.2.38.2 Description No. 2**

This service feature allows the served user to apply different call treatments based on time of day, day of week, day of year, holiday, etc.
