Recomendación UIT-T T.415

(Anteriormente «Recomendación del CCITT»)

PREFACIO

La UIT (Unión Internacional de Telecomunicaciones) es el organismo especializado de las Naciones Unidas en el campo de las telecomunicaciones. El UIT-T (Sector de Normalización de las Telecomunicaciones de la UIT) es un órgano permanente de la UIT. En el UIT-T, que es la entidad que establece normas mundiales (Recomendaciones) sobre las telecomunicaciones, participan unos 179 países miembros, 84 empresas de explotación de telecomunicaciones, 145 organizaciones científicas e industriales y 38 organizaciones internacionales.

Las Recomendaciones las aprueban los Miembros del UIT-T de acuerdo con el procedimiento establecido en la Resolución N.º 1 de la CMNT (Helsinki, 1993). Adicionalmente, la Conferencia Mundial de Normalización de las Telecomunicaciones (CMNT), que se celebra cada cuatro años, aprueba las Recomendaciones que para ello se le sometan y establece el programa de estudios para el periodo siguiente.

En ciertos sectores de la tecnología de la información que corresponden a la esfera de competencia del UIT-T, se preparan las normas necesarias en colaboración con la ISO y la CEI. El texto de la Recomendación UIT-T T.415 se aprobó por la CMNT (Helsinki, 1-12 de marzo de 1993). Su texto se publica también, en forma idéntica, como Norma Internacional ISO/CEI 8613-5.

NOTAS

1) Como consecuencia de un proceso de reforma interna de la Unión Internacional de Telecomunicaciones (UIT), desde el 28 de febrero de 1993 ya no existe el CCITT. En su lugar, se creó el Sector de Normalización de las Telecomunicaciones de la UIT (UIT-T), con vigencia a partir del primero de marzo de 1993. De modo similar, en este proceso de reforma, el CCIR y la IFRB han sido sustituidos por el Sector de Radiocomunicaciones.

Con el fin de no retrasar la publicación de la presente Recomendación, no se han cambiado en el texto las referencias que contienen los acrónimos «CCITT, CCIR o IFRB» ni sus entidades relacionadas tales como Asamblea Plenaria, Secretaría, etc. Las futuras ediciones de la presente Recomendación contendrán la terminología apropiada relacionada con la nueva estructura de la UIT.

2) En esta Recomendación, la expresión «Administración» se utiliza para designar, en forma abreviada, tanto una Administración de telecomunicaciones como una empresa de explotación reconocida de telecomunicaciones.

Introducción

Esta Recomendación UIT-T | Norma Internacional fue preparada como publicación conjunta por la Comisión de Estudio VIII del CCITT y el Comité Técnico Mixto 1 ISO/CEI.

Actualmente, las Recomendaciones de la serie UIT-T T.410 | Norma Internacional ISO/CEI 8613 son las siguientes:

- introducción y principios generales;
- estructuras de documento;
- perfil de documento;
- formato de intercambio de documento abierto;
- arquitecturas de contenido de caracteres;
- arquitecturas de contenido de gráficos por puntos;
- arquitecturas de contenido de gráficos geométricos;
- especificación formal de la arquitectura de documento abierta (FODA).
(La especificación formal es aplicable únicamente a ISO/CEI 8613.)

Podrían añadirse otras Recomendaciones | Normas Internacionales a esta serie de Recomendaciones | Norma Internacional.

La elaboración de esta serie de Recomendaciones | Normas Internacionales se hizo inicialmente en paralelo con la norma ECMA-101: *Open Document Architecture*.

Esta serie de Recomendaciones | Normas Internacionales es una nueva edición de la serie de Recomendaciones T.410 del CCITT (1988) e ISO/CEI 8613: (1989).

Cambios técnicos significativos son la inclusión de las siguientes modificaciones acordadas por el CCITT e ISO/CEI:

- representación alternativa;
- anexo sobre la utilización de MHS/MOTIS;
- color;
- anexo sobre pruebas de conformidad;
- perfil de aplicación de documento, formulario y notación;
- seguridad;
- trenes;
- estilos;
- gráficos por puntos enlosados.

Además, se han aplicado algunos corrigendos técnicos a esta Recomendación | Norma Internacional.

Esta Recomendación | Norma Internacional contiene siete anexos:

- Anexo A (no integrante): Representación codificada;
- Anexo B (no integrante): Aplicaciones de rótulos de clase de aplicación;
- Anexo C (no integrante): Sumario de identificadores de objeto;
- Anexo D (no integrante): Ejemplos;
- Anexo E (integrante): Lenguaje de documento abierto (ODL) (este anexo es aplicable únicamente a ISO/CEI 8613-5);
- Anexo F (no integrante): Ejemplos de representaciones en lenguaje de documento abierto (este anexo es aplicable únicamente a ISO/CEI 8613-5);
- Anexo G (no integrante): Utilización del tipo de codificación distinguida o canónica.

NORMA INTERNACIONAL

RECOMENDACIÓN UIT-T

**TECNOLOGÍA DE LA INFORMACIÓN –
ARQUITECTURA DE DOCUMENTO ABIERTA Y FORMATO DE INTERCAMBIO:
FORMATO DE INTERCAMBIO DE DOCUMENTO ABIERTO**

1 Objeto

Las Recomendaciones UIT-T de la serie T.410 | ISO/CEI 8613 tienen por objeto facilitar el intercambio de documentos.

En el contexto de estas Recomendaciones | Normas Internacionales, se considera que los documentos son elementos tales como memorandos, cartas, facturas, formularios e informes, que pueden incluir imágenes y material tabulado. Los elementos de contenido utilizados en los documentos pueden incluir caracteres gráficos, elementos gráficos geométricos y elementos gráficos por puntos, todos los cuales pueden estar presentes en un mismo documento.

NOTA – Estas Recomendaciones | Normas Internacionales están concebidas de manera que admitan ampliaciones, tales como características de hipermedios, hojas de cálculo y otros tipos de contenido, tales como sonido y vídeo.

Además de los tipos de contenido definidos en estas Recomendaciones | Normas Internacionales, la arquitectura de documento abierta (ODA, *open document architecture*) también permite la inclusión en los documentos de tipos de contenido arbitrarios.

Estas Recomendaciones | Normas Internacionales se aplican al intercambio de documentos por medio de comunicaciones de datos o por intercambio de medios de almacenamiento.

Estas Recomendaciones | Normas Internacionales permiten el intercambio de documentos con uno o ambos de los fines siguientes:

- permitir la presentación prevista por el originador;
- permitir su procesamiento, con fines tales como edición y reformatación.

La composición de un documento en intercambio puede adoptar varias formas:

- formatada, que permite la presentación del documento;
- procesable, que permite el procesamiento del documento;
- formatada procesable, que permite la presentación y el procesamiento del documento.

Estas Recomendaciones | Normas Internacionales también permiten el intercambio de las estructuras de información ODA utilizadas para el procesamiento de los documentos intercambiados.

Esta Recomendación | Norma Internacional define:

- el formato del tren de datos utilizado para intercambiar documentos estructurados de acuerdo con la Recomendación UIT-T T.412 | ISO/CEI 8613-2;
- la representación de los constituyentes que pueden aparecer en un documento intercambiado.

NOTAS

1 Esta Recomendación UIT-T | Norma Internacional no especifica la representación codificada de elementos de contenido.

2 Los formatos de datos para atributos de presentación y atributos de codificación se definen en otras Recomendaciones UIT-T de la serie T.410 | ISO/CEI 8613.

2 Referencias normativas

Las siguientes Recomendaciones y Normas Internacionales contienen disposiciones que, mediante su referencia en este texto, constituyen disposiciones de la presente Recomendación | Norma Internacional. Al efectuar su publicación, las ediciones indicadas eran válidas. Todas las Recomendaciones y Normas son objeto de revisiones, por lo que se

preconiza que los participantes en acuerdos basados en esta Recomendación | Norma Internacional investiguen la posibilidad de aplicar las ediciones más recientes de las Recomendaciones y Normas indicadas. Los miembros de la CEI y la ISO mantienen registros de las Normas Internacionales en vigor. La Oficina de Normalización de las Telecomunicaciones del UIT mantiene una lista de las Recomendaciones UIT-T actualmente válida.

2.1 Recomendaciones | Normas Internacionales idénticas

¹⁾ Actualmente en estado de proyecto.

3 Definiciones

Para los fines de esta Recomendación | Norma Internacional, se aplican las definiciones indicadas en la Recomendación UIT-T T.411 | ISO/CEI 8613-1.

Además, se aplican a esta Recomendación | Norma Internacional las definiciones de la Rec. X.208 del CCITT | ISO/CEI 8824 y la Rec. X.209 del CCITT | ISO/CEI 8825.

4 Abreviaturas

Para los fines de esta Especificación, se aplican las abreviaturas indicadas en la Rec. UIT-T.411 | ISO/CEI 8613-1.

Para los fines de esta Especificación se aplican las siguientes abreviaturas adicionales:

DTD	Definición de tipo de documento (<i>document type definition</i>)
EOC	Fin de contenido (<i>end of contents</i>)
GI	Identificador genérico SGML (<i>SGML generic identifier</i>)
IA5	Alfabeto internacional N.º 5 (<i>international alphabet No. 5</i>)
ID	Identificador único SGML (<i>SGML unique identifier</i>)
LIT	Comienzo o fin de literal (<i>literal start or end</i>)
LITA	Comienzo o fin de literal (alternativo) [<i>literal start or end (alternative)</i>]
LPD	Definición de proceso de enlace (<i>link process definition</i>)
OSI	Interconexión de sistemas abiertos (<i>open systems interconnection</i>)
ULA	Aplicaciones de capa alta (<i>upper layer applications</i>)
UTC	Tiempo universal coordinado (<i>coordinated universal time</i>)

5 Convenios

Para los fines de esta Especificación, se aplican los convenios indicados en la Rec. UIT-T T.411 | ISO/CEI 8613-1.

6 Representaciones de documento

Un documento estructurado con arreglo a las Recomendaciones UIT-T de la serie T.410 | ISO/CEI 8613 es representado para intercambio sea en el formato de intercambio de documento abierto (ODIF), o en el lenguaje de documento abierto (ODL), en unión del formato de intercambio de documento SGML (SDIF). Las representaciones ODIF y ODL/SDIF son técnicamente equivalentes; un documento puede ser transformado de una a otra sin pérdida de información semántica en cuanto a los constituyentes y atributos del documento.

La utilización de ODL y SDIF es aplicable únicamente a ISO/CEI 8613.

NOTA – Ambas representaciones en estructura de datos (ODIF) y en lenguaje (ODL) se han normalizado a fin de satisfacer los requisitos de representación de documentos en los distintos entornos de aplicación. ODIF, al ser una estructura de datos especificada utilizando ASN.1, está particularmente destinado a su utilización en un entorno OSI. ODL es particularmente apropiado para sistemas que comparten información a través de ficheros de texto marcados, especialmente cuando usuarios humanos pueden acceder directamente al marcado.

6.1 ODIF

ODIF es una sintaxis de datos abstracta en la que los constituyentes y atributos del documento están representados por una jerarquía de estructuras de datos e ítem de datos, especificados utilizando la notación de sintaxis abstracta ASN.1 definida en la Rec. UIT-T X.208 | ISO/CEI 8824.

La representación codificada de cada estructura de datos o elementos de datos se obtiene aplicando un conjunto de reglas de codificación.

ODIF se especifica en la cláusula 7.

NOTA – ASN.1 es un método de descripción formal que permite especificar tipos de datos pertinentes para una aplicación en términos de otros tipos de datos, incluidos tipos de datos básicos tales como «entero» y «cadena de octetos» que se definen en la propia Rec. UIT-T X.208 | ISO/CEI 8824. Las reglas de codificación básica para la ASN.1 se definen en la Rec. UIT-T X.209 del CCITT | ISO/CEI 8825 y se suman en el Anexo A.

6.2 ODL y SDIF

La utilización de ODL y SDIF es aplicable únicamente a ISO/CEI 8613.

ODL es un lenguaje en el que los constituyentes y atributos del documento son identificados por rótulos descriptivos, y se agrupan en una o más entidades de almacenamiento (por ejemplo, ficheros) según las necesidades del usuario.

En el intercambio, cada entidad ODL es representada por una única estructura de datos o ítem de datos, especificado utilizando ASN.1, en un tren de datos construido con arreglo al formato de intercambio de documento SGML definido en ISO 9069.

ODL se especifica en el Anexo E (normativo).

NOTA – ODL es una aplicación SGML conforme a ISO 8879.

7 Formato de intercambio de documento abierto (ODIF)

7.1 Descripción general

Un documento estructurado de acuerdo con las Recomendaciones UIT-T de la serie T.410 | ISO/CEI 8613 se representa por un tren de datos constituido por una o más estructuras de datos de los siguientes tipos:

- descriptor de perfil de documento;
- descriptor de objeto disposición;
- descriptor de clase de objeto de disposición;
- descriptor de objeto lógico;
- descriptor de clase de objeto lógico;
- descriptor de estilo de presentación;
- descriptor de estilo de disposición;
- unidad de texto;
- descriptor de perfil de documento sellado;
- descriptor de perfil de documento cifrado;
- descriptor de parte de cuerpo de documento precifrado;
- descriptor de parte de cuerpo de documento poscifrado.

Estas estructuras de datos se denominan *elementos de datos de intercambio*. Dentro de un tren de datos, los elementos de datos de intercambio se ordenan de acuerdo con ciertas reglas que se especifican más adelante. Esta Especificación define dos de estos conjuntos de reglas, que se denominan *clase A de formato de intercambio* y *clase B de formato de intercambio*.

En el descriptor de perfil de documento se indica cuál de estos dos conjuntos de reglas se aplica a un determinado tren de datos. En todos los casos, un tren de datos contiene un descriptor de perfil de documento, y sólo uno, que es siempre el primer elemento de datos de intercambio del tren de datos. El descriptor del perfil de documento puede ser la única estructura de datos del tren de datos.

Cuando un tren de datos ODIF se utiliza como parte de un tipo de datos externo ASN.1, la sintaxis abstracta estará formada por un tipo *secuencia de SEQUENCE OF ASN.1*, que hace referencia al tipo de **elemento de datos de intercambio (Interchange-Data-Element)**; la codificación del valor de datos constará de un número entero de octetos, formados aplicando las reglas de codificación básicas ASN.1; y el valor del identificador de objeto asociado será **{ 2 8 0 0 }**.

NOTA – Esta Especificación no define la manera de incorporar los elementos de datos de intercambio, ni el tipo de datos externos, en un protocolo de aplicación, ni la manera de establecer la correspondencia de éstos con las unidades de datos de servicio (en un entorno OSI).

7.2 Clase A de formato de intercambio

Según la clase A de formato de intercambio, un tren de datos está constituido por un descriptor de perfil de documento y, opcionalmente, uno o más elementos de datos de intercambio de los siguientes tipos:

- descriptor de objeto de disposición;
- descriptor de clase de objeto de disposición;
- descriptor de objeto lógico;
- descriptor de clase de objeto lógico;
- descriptor de estilo de presentación;
- descriptor de estilo de disposición;
- unidad de texto;
- descriptor de perfil de documento sellado;
- descriptor de perfil de documento cifrado;
- descriptor de parte de cuerpo de documento precifrado;
- descriptor de parte de cuerpo de documento poscifrado.

El orden de los elementos de datos de intercambio es el siguiente:

- a) descriptor de perfil de documento;
- b) descriptores de clase de objeto de disposición;
- c) descriptores de clase de objeto lógico;
- d) unidades de texto que representan porciones de contenido genérico;
- e) descriptores de estilo de presentación;
- f) descriptores de estilo de disposición;
- g) descriptores de objeto de disposición;
- h) descriptores de objeto lógico;
- i) unidades de texto que representan porciones de contenido específico;
- j) descriptores de perfil de documento sellados;
- k) descriptores de perfil de documento cifrados;
- l) descriptores de parte de cuerpo de documento precifrados;
- m) descriptores de parte de cuerpo de documento poscifrados.

Dentro de cada uno de los grupos de descriptores de objeto de disposición y de descriptores de objeto lógico, el orden de los descriptores es igual al orden secuencial definido en la Rec. UIT-T T.412 | ISO/CEI 8613-2.

Si el tren de datos contiene descriptores de objeto de disposición, las unidades de texto que representan porciones de contenido específico se ordenan según el orden de disposición secuencial; en otro caso, se ordenan según el orden lógico secuencial.

Dentro de cada uno de los demás grupos de elementos de datos de intercambio, el orden es arbitrario.

Para los objetos básicos que tienen especificadas descripciones alternativas, hay un descriptor que representa la descripción primaria y un descriptor para cada descripción alternativa. En el tren de datos, los descriptores correspondientes a descripciones alternativas de descripciones de objeto básico vienen inmediatamente después de los descriptores de su descripción primaria, por orden de preferencia decreciente. Las unidades de texto que representan las porciones de contenido asociadas a los subárboles alternativos siguen inmediatamente después de las que representan las porciones de contenido asociadas al subárbol primario, en el orden de preferencia decreciente.

7.3 Clase B de formato de intercambio

Según la clase B de formato de intercambio, un tren de datos está constituido por un descriptor de perfil de documento y, opcionalmente, uno o más elementos de datos de intercambio de los siguientes tipos:

- descriptor de objeto de disposición;
- descriptor de clase de objeto de disposición;
- descriptor de estilo de presentación;

ISO/CEI 8613-5 : 1994 (S)

- unidad de texto;
- descriptores de perfil de documento sellados;
- descriptores de perfil de documento cifrados;
- descriptores de parte de cuerpo de documento poscifrados.

La clase B de formato de intercambio puede utilizarse sólo para representar documentos que no contengan ninguna estructura lógica específica ni genérica, es decir, documentos que se ajusten a la clase de arquitectura de documento formatada.

NOTA – La clase B de formato de intercambio se proporciona únicamente para utilización con el perfil de aplicación de documento en el intercambio de documentos facsímil del grupo 4, como se especifica en la Recomendación UIT-T T.503.

El orden de los elementos de datos de intercambio es el siguiente:

- a) descriptor de perfil de documento;
- b) descriptores de clase de objeto de disposición y unidades de texto asociadas;
- c) descriptores de estilo de presentación;
- d) descriptores de objeto de disposición y unidades de texto asociadas;
- e) descriptores de perfil de documento sellados;
- f) descriptores de perfil de documento cifrados;
- g) descriptores de parte de cuerpo de documento poscifrados.

Dentro del grupo de descriptores de clase de objeto de disposición y unidades de texto asociadas, el orden es tal que un grupo de descriptores que tienen identificadores idénticos, excepto el último número de cada identificador, se siguen entre sí en el tren de datos sin ningún otro descriptor entre ellos. Sin embargo, cada descriptor de una clase de objeto para un objeto de disposición básico va seguido inmediatamente por las unidades de texto asociadas.

Dentro del grupo de descriptores de objeto de disposición y unidades de texto asociadas, el orden de los descriptores es igual al orden secuencial definido en la Rec. UIT-T T.412 | ISO/CEI 8613-2. Sin embargo, cada descriptor de un objeto de disposición básico va seguido inmediatamente por las unidades de texto asociadas.

Dentro del grupo de descriptores de estilo de presentación, el orden es arbitrario.

7.4 Descriptores y unidades de texto

Un descriptor de perfil de documento, descriptor de objeto de disposición, descriptor de clase de objeto de disposición, descriptor de objeto lógico, descriptor de clase de objeto lógico, descriptor de estilo de presentación, descriptor de estilo de disposición, descriptor de perfil de documento sellado, descriptor de perfil de documento cifrado, descriptor de parte de cuerpo de documento precifrado o descriptor de parte de cuerpo de documento poscifrado consta de ítems de datos simples y compuestos que representan los atributos del constituyente considerado.

El perfil de documento, cada clase de objeto, cada estilo, cada objeto y cada parte protegida se representa por un descriptor.

Una unidad de texto consta de dos partes:

- a) un campo de atributo, es decir, una estructura de datos constituida por ítems de datos simples y compuestos que representan los atributos de la porción de contenido considerada;
- b) un campo de información, es decir, una estructura de datos que es un ítem de datos o un conjunto de ítems de datos que representan los elementos de contenido que componen la porción de contenido considerada.

Cada porción de contenido viene representada por una unidad de texto.

Los formatos de datos de los elementos de datos de intercambio se especifican en 7.6 a 7.15, utilizando la notación de sintaxis abstracta ASN.1 definida en la Rec. UIT-T X.208 | ISO/CEI 8824.

NOTA – Las subcláusulas 7.6 a 7.15 no definen completamente por sí mismos el formato del tren de datos; en 7.1 a 7.5 de esta Especificación y en otras Especificaciones de las Recomendaciones de la serie UIT-T T.410 | ISO/CEI 8613 se especifican reglas adicionales. Por ejemplo, la palabra clave **OPTIONAL** indica simplemente que una determinada estructura de datos o un determinado ítem de datos no forma parte de cada instancia de la estructura de datos continente; las condiciones que controlan la presencia o ausencia de la estructura de datos o del ítem de datos se especifican en la Rec. UIT-T T.412 o T.414 | ISO/CEI 8613-2 ó 8613-4.

7.5 Técnicas de codificación ASN.1 y criptográficas

7.5.1 Información cifrada

Las partes del cuerpo del documento o las partes del perfil de documento que son el resultado de un proceso de cifrado formarán un nuevo constituyente del documento. Consta de un identificador y la información cifrada. La última es del tipo **OCTET STRING** de ASN.1, cuyo valor permanecerá inalterado en cualquier transferencia.

7.5.2 Información sellada

Los atributos de seguridad de ODA y las partes de documento de ODA se definen en ASN.1. Para asegurar una codificación única de ASN.1, se utilizan las reglas de codificación distinguidas o canónica de ASN.1. Estas reglas se definen en la Rec. UIT-T X.209-3 | ISO/CEI 8825-3 y la información sobre cómo pueden utilizarse en el Anexo G. Las reglas de codificación distinguida y canónica de ASN.1 especifican un conjunto de restricciones de las reglas de codificación básicas de ASN.1, que proporcionan una correspondencia única entre ASN.1 y su representación. Esto se requiere desde un punto de vista criptográfico.

La principal diferencia entre las reglas de codificación distinguida y canónica son que las primeras utilizan una codificación de longitud definida, mientras que las últimas utilizan longitud indefinida. Las reglas de codificación distinguida son más adecuadas si el valor codificado es suficientemente pequeño para encajar en la memoria disponible, y existe necesidad de saltar rápidamente sobre algunos valores anidados. Las reglas de codificación canónica son más adecuadas, y existe necesidad de codificar valores que sean tan grandes que no puedan fácilmente encajar en la memoria disponible, o es necesario codificar y transmitir parte de un valor antes de que esté disponible el valor completo.

Las partes de perfil de documento y las partes de cuerpo de documento sujetas a sellado permanecen inalteradas después del proceso de sellado. Las reglas de codificación distinguidas ASN.1 asegurarán que el destinatario pueda establecer la misma codificación de la información que la utilizada por el originador en el sellado. Esto es necesario para obtener huellas dactilares idénticas de la información, que es la manera de asociar el contenido al sello.

El sello se compone de un conjunto de datos. Su generación se efectúa en tres etapas básicas:

- a) La información elegida (codificada utilizando las reglas de codificación distinguida o canónica ASN.1 de acuerdo con el atributo de perfil de documento «codificación de información sellada») es la entrada a un proceso de desmenuzamiento que genera una huella dactilar. La forma codificada de la huella dactilar es una CADENA DE OCTETOS (**OCTET STRING**).
- b) Al conjunto de la huella dactilar y la información opcional adicional se le llama **información sellada (Sealed-Information)**. Los parámetros opcionales son la fecha y la hora del día, de acuerdo con ISO 8601, el nombre y el lugar del creador del sello. Esto es la entrada (codificada una vez más utilizando las reglas de codificación distinguidas o canónicas ASN.1 de acuerdo con el atributo de perfil de documento «codificación de información sellada») a un proceso criptográfico que genera el sello. La forma codificada del sello es una CADENA DE OCTETOS (**OCTET STRING**).
- c) Provisión de información sobre el método de sellado de modo que pueda verificarse el sello. Se especifica en el tipo de **método de sellado (Seal-Method)** y consta de información sobre la generación de la huella dactilar y sobre cómo descifrar el sello.

El orden de los constituyentes es igual al especificado por la clase de formato de intercambio.

Cuando el orden de los constituyentes no se especifica completamente mediante la clase de formato de intercambio, se aplican las reglas siguientes:

- las clases de objeto deben sellarse en el mismo orden que están especificadas en el parámetro «constituyentes sellados»;
- para la clase de formato de intercambio A, las porciones de contenido común han de sellarse en el mismo orden que las clases de objeto correspondientes;
- los estilos de presentación deben sellarse en el mismo orden que están especificados en el parámetro «constituyentes sellados»;
- los estilos de disposición deben sellarse en el mismo orden que están especificados en el parámetro «constituyentes sellados».

Anexo A

Representación codificada

(Este anexo no es parte integrante de esta Recomendación | Norma Internacional)

Este anexo es un sumario de las reglas de codificación básicas para la notación de sintaxis abstracta uno (ASN.1) definida en la Rec. UIT-T T.209 | ISO/CEI 8825.

La representación codificada de cada estructura de datos o ítem de datos que constituye la totalidad, o parte, de un descriptor o una unidad de texto consta de un campo de tipo, un campo de longitud y un campo de valor.

Si el ítem de datos considerado es un ítem de datos elemental, entonces el campo de tipo especifica el tipo de dato elemental, el campo de longitud especifica la longitud del campo de valor, y el campo de valor representa el valor del ítem de datos.

Si la estructura de datos o el ítem de datos considerado no es elemental, entonces el campo de tipo identifica el atributo o el grupo de atributos que corresponden a la estructura de datos o al ítem de datos, el campo de longitud especifica la longitud del campo de valor, y el campo de valor consta de uno o más tríos, cada uno de los cuales se compone de un campo de tipo, un campo de longitud y un campo de valor, que representan las estructuras de datos y los ítem de datos subordinados.

El *campo de tipo* (denominado «octetos de identificador» en la Rec. UIT-T X.209 | ISO/CEI 8825) consta de uno o más bytes. Los bits del primer byte se utilizan como sigue:

bits 8 y 7: clase de rótulo (00: universal,
01: aplicación,
10: específico del contexto,
11: privado);

bit 6: forma de codificación de contenido (0: simple,
1: estructurada);

bits 5 a 1: 00000 a 11110: número de rótulo;
11111 indica un campo de tipo multiocteto.

En la Recomendación X.208 del CCITT | ISO/CEI 8824 y Recomendación X.209 del CCITT | ISO/CEI 8825 se han asignado los números de rótulo para rótulos universales como se indica en el Cuadro A.1.

Cuadro A.1 – Rótulos de clase universales

Tipos de datos incorporados	Tipos de datos definidos
0: fin de contenido	18: cadena numérica
1: booleano	19: cadena imprimible
2: entero	20: cadena teletex
3: cadena de bits	21: cadena de videotex
4: cadena de octetos	22: cadena IA5
5: nulo	23: tiempo UTC
6: identificador de objeto	24: tiempo generalizado
7: descriptor de objeto	25: cadena de caracteres gráficos
8: externo	26: cadena general
9: real	27: cadena visible
10: enumerado	
11: encriptado	
16: secuencia	
17: conjunto	

Los ítem de datos de tipo fin de contenido, booleano, entero o nulo son simples (ítem de datos elementales). Las secuencias y los conjuntos son estructurados (estructuras de datos con ítem de datos subordinados). Los ítem de datos tipo cadena de bits, cadena de octetos y cualquiera de los tipos de datos definidos pueden ser simples o estructurados.

ISO/CEI 8613-5 : 1994 (S)

El *campo de longitud* está constituido por uno o más bytes, y adopta una de estas tres formas: corta, larga e indefinida. Los bits del primer byte se utilizan como sigue:

- bit 8: forma del campo de longitud (0: corta,
1: larga o indefinida);
- bits 7 a 1: si el bit 8 = 0: número de bytes del campo de valor;
si el bit 8 = 1: número de bytes del campo de longitud que sigue al primer octeto;
0000000 indica que el campo de longitud es de forma indefinida.

Una estructura de datos o un ítem de datos o un campo de longitud indefinida tiene que ser estructurado y tiene que ser terminado por un delimitador constituido por un ítem de fin de contenido (EOC). Un ítem EOC consta de dos bytes: un campo de tipo de un byte y un campo de longitud de un byte. Ambos son iguales a cero. Un ítem EOC no tiene campo de valor.

Anexo B**Asignaciones de rótulos de clase de aplicación**

(Este anexo no es parte integrante de esta Recomendación | Norma Internacional)

Las asignaciones de rótulo de clase de aplicación que se hacen en diversas cláusulas de esta Especificación se sumarian en el Cuadro B.1.

Cuadro B.1 – Rótulos de clase de aplicación

Rótulo	Tipo de datos	Referencia (subcláusula)
APLICACIÓN 0	Identificador de porción de contenido	7.8
APLICACIÓN 1	Identificador de objeto o clase	7.8
APLICACIÓN 2	Tipo de contenido	7.11
APLICACIÓN 3	Datos de caracteres	7.7
APLICACIÓN 4	Fecha y hora	7.7
APLICACIÓN 5	Identificador de estilo	7.8
APLICACIÓN 6	Nombre de persona	7.7
APLICACIÓN 7	Identificador de parte protegida	7.8

Anexo C

Sumario de identificadores de objeto

(Este anexo no es parte integrante de esta Recomendación | Norma Internacional)

Los valores de los identificadores de objeto ASN.1 se asignan en diversos puntos de esta Recomendación. Estos se resumen en el Cuadro C.1.

Cuadro C.1 – Sumario de identificadores de objeto ASN.1

Valor del identificador de objeto	Significado	Cláusula
{ 2 8 0 0 }	Identifica el tipo de datos externos	7.1
{ 2 8 1 5 5 }	Identifica el módulo elementos de datos de intercambio	7.6
{ 2 8 1 5 6 }	Identifica el módulo descriptor de perfil de documento	7.7
{ 2 8 1 5 7 }	Identifica el módulo identificadores y expresiones	7.8
{ 2 8 1 5 8 }	Identifica el módulo descriptores de disposición	7.9
{ 2 8 1 5 9 }	Identifica el módulo descriptores lógicos	7.10
{ 2 8 1 5 10 }	Identifica el módulo descriptores de estilo	7.11
{ 2 8 1 5 11 }	Identifica el módulo listas de valores por defecto	7.12
{ 2 8 1 5 12 }	Identifica el módulo unidades de texto	7.13
{ 2 8 1 5 13 }	Identifica el módulo descriptores de parte protegida	7.15
{ 2 8 1 5 14 }	Identifica el módulo atributos de color	7.14

Anexo D

Ejemplos

(Este anexo no es parte integrante de esta Recomendación | Norma Internacional)

Los cuatro primeros ejemplos de este anexo están constituidos por trenes de datos que representan diferentes versiones del espécimen de documento del Anexo B de la Recomendación UIT-T T.412 | ISO/CEI 8613-2.

Se consideran cuatro versiones del espécimen de documento:

- Ejemplo 1: únicamente estructura de disposición específica. Este ejemplo es especificado por B.4.1, incluidos la Figura B.7 y el Cuadro B.1 de la Rec. UIT-T T.412 | ISO/CEI 8613-2.
- Ejemplo 2: únicamente estructura lógica específica. Este ejemplo es especificado por B.4.2, incluidos la Figura B.8 y los cuadros B.2 y B.3 de la Rec. UIT-T T.412 | ISO/CEI 8613-2.
- Ejemplo 3: estructura lógica específica, estructura lógica genérica y estructura de disposición genérica. Este ejemplo es especificado por B.5, incluidos las Figuras B.8, B.9 y B.10, y los Cuadros B.4, B.5, B.6 y B-7 de la Rec. UIT-T T.412 | ISO/CEI 8613-2.
- Ejemplo 4: únicamente estructura de disposición específica generada a partir de las estructuras del ejemplo 3. Este ejemplo es especificado por B.6, incluidos la Figura B.11 y el Cuadro B.8 de la Rec. UIT-T T.412 | ISO/CEI 8613-2.

Los cuatro ejemplos se presentan más adelante en D.1, D.2, D.3 y D.4. El tren de datos que constituye cada ejemplo se muestra en dos formas de notación:

- a) la notación ASN.1 para valores de datos definidos en la Rec. UIT-T X.208 | ISO/CEI 8824;
- b) la notación hexadecimal de los valores de los datos codificados, después de aplicar las reglas de codificación básicas definidas en la Rec. UIT-T X.209 | ISO/CEI 8825.

La notación ASN.1 se presenta a la izquierda y la notación hexadecimal a la derecha de cada página. El símbolo **LL** representa un campo de longitud del cual se desconoce la longitud.

NOTA – Los trenes de datos ODL equivalentes a estos ejemplos se presentan en el Anexo F.

Además, D.5 presenta un ejemplo constituido por un tren de datos que representa el perfil del espécimen de documento del Anexo C a la Rec. UIT-T T.414 | ISO/CEI 8613-4.

D.1 Ejemplo 1: Especimen de documento extraído del Anexo B de la Rec. UIT-T T.412 | ISO/CEI 8613-2; únicamente estructura de disposición específica

Anexo E

Lenguaje de documento abierto (ODL, open document language)

(Este anexo es parte integrante de esta Norma Internacional)

This annex is applicable to ISO/IEC 8613-5 only.

NOTE – To maintain correspondence in clause numbering between ITU-T Recommendation T.415 and ISO/IEC 8613-5, this portion of the Open Document Language (ODL) is specified in a normative annex rather than in the body of this Specification.

E.1 Introduction

This annex specifies a standardized SGML representation of ODA documents, known as the Open Document Language (ODL). ODL is an SGML application conforming to ISO 8879.

This annex also includes rules for using the SGML Document Interchange Format (SDIF) for ODA/ODL documents.

The definitions of ISO 8879 apply to this annex.

NOTES

1 ODL applies SGML to the representation of ODA documents. The specification of ODL focuses on areas that require significant choices to be made: it does not attempt to restate the normal rules of either SGML or ODA for “business as usual”. Therefore, if an item is not discussed explicitly:

- a) On issues of semantics, normal ODA rules apply (e.g. allowable attribute values).
- b) On issues of syntax, normal SGML rules apply (e.g. formulation of generic identifiers). Frequently, these rules allow wide latitude to an implementation with no adverse effect on interchange.

For example, SGML requires object class identifiers (element type names, or “generic identifiers (GIs)”) to be unique to an element type and to conform to certain syntactic rules. An ODL implementation could, therefore, generate GIs sequentially (G1, G2, ..., Gn). E.2.2.6, however, recommends that GIs be based on (“normally derived from”) user-visible names. The preferred “derivation” obviously would be to use the user-visible name “as is” as the GI, but where this is not possible (none specified, not unique, or non-compliance with syntax), an implementation would generate a different name. (Note that there is no constraint on the user-visible name itself; only on the GI.)

2 SGML applications are classified as “structure-controlled” if they operate on the structure that the markup describes, or “markup-sensitive” if they operate on the markup itself. The ODA layout process is a structure-controlled application, while editing an ODA document or converting it from one interchange format to another are markup-sensitive.

The ODL specification defines the precise representation of all ODA processing semantics, thereby permitting “round trips” between ODIF and ODL that will yield the same processing fidelity for structure-controlled applications as interchange with a single format. However, several non-semantic ODA attributes that are used only in markup-sensitive applications are represented using a single SGML construct called a “comment”. The means by which these kinds of information are distinguished from one another in ODL is left to the implementation (e.g. both user-visible names and user-readable comments are representable as SGML comments, but an implementation could distinguish between the two by a convention such as beginning the comment with “**URC:**” or “**UVN:**”).

3 For both ODIF and ODL, the base notation parser (ASN.1 or SGML) must be supplemented by ODA-specific parsers. For example, an ODIF parser must validate and resolve cross-references to ODA object identifiers, a function that is an intrinsic part of an SGML parser. An ODL parser, however, will need to segregate components of an attribute value with constructed parameters, which is done intrinsically by ASN.1. In some cases, both ODIF and ODL parsers will need to accomplish the same task, such as resolving defaulted attribute values. (A system that supported both could probably do such tasks with common code.)

4 In both ODIF and SDIF, content portions are normally represented in the ASN.1 data stream as distinct structure components, corresponding, in the case of SDIF, to data entities. In the case of character content, this technique avoids the problem – inherent in all character-based parsing – of data characters that could confuse the parsers. ODL/SDIF can, therefore, represent multiple character sets and control characters to the same extent as ODIF (and with the same efficiency, since both use ASN.1 to demark content portions). (The way in which an implementation treats separate entities within its own environment is not constrained by any standard.)

ODL, however, like other properly-designed SGML applications, also offers the technique of including character content in the same entity as the markup. This technique can be employed for those content portions in which none of the characters conflict with the concrete syntax chosen by the implementation. ISO 8879 contains an extensive discussion of this subject, along with two “multicode” concrete syntax definitions intended for use in multiple character set environments.

E.2 Fundamentals

E.2.1 Basic objects and their content

In ODA, a basic object can have the attribute “content portions” and cannot have the attribute “subordinates”. In the ODL representation of ODA, all content portions occur in “data elements”.

ISO/CEI 8613-5 : 1994 (S)

A data element is an element that is declared either to be empty, or to contain only data. An application should normally define at least one data element type for each content architecture class in use.

NOTE – Definitions for “generic” data elements are given in E.10.2.1 and E.10.2.2. Specialized data element types could also be defined. For example, see the element declaration for “**logo**” in F.1.2.2.

In the layout structure, a data element is itself a basic object. In the logical structure, however, a data element is the sole subelement of a basic object. Attributes of a basic object that are dependent on the content architecture (such as presentation attributes) are represented as attributes of its data element.

A content model for a basic logical object normally offers a choice of all possible data element types (and therefore content architecture classes), as in:

```
<!ELEMENT blo O O (cf | cfp | cp | gfp | rf | rfp) >
```

An instance of a basic logical object, however, can contain only a single data element.

E.2.2 ODL names

ODL names are used as generic identifiers of element types, in attribute values, and in the construction of certain data content notation and attribute names.

NOTE – In some SGML concrete syntaxes, including the reference concrete syntax, case distinctions in names other than entity names are not significant. The names defined in ODL are unique even in such syntaxes.

E.2.2.1 Logical object type names

The ODL names for the logical object types are the short form human-readable names defined in A.2.5 of ITU-T Rec. T.412 | ISO/IEC 8613-2:

DLOR -- *document logical root*
CLO -- *composite logical object*
BLO -- *basic logical object*

E.2.2.2 Layout object type names

The ODL names for the layout object types are the short form human-readable names defined in A.2.5 of ITU-T Rec. T.412 | ISO/IEC 8613-2, with two exceptions noted below:

DLAR -- *document layout root*
PAGES -- *page set (Exception: equivalent to PAGE_SET)*
PAGE -- *page (composite)*
BPAGE -- *page (basic) (Exception: see Note.)*
FRAME -- *frame*
BLOCK -- *block*

NOTE – For syntactic convenience, an object of the type ‘composite or basic page’ is given the ODL object type name **PAGE** when it is a composite page and the ODL object type name **BPAGE** when it is a basic page. This technique allows composite and basic pages to be represented in ODL as distinct element types, with the appropriate attributes defined for each.

E.2.2.3 Content architecture class names

ODL names for content architecture classes are defined in the Specifications in ISO/IEC 8613 where the SGML representations of the content-related attributes are defined.

Those defined at present are:

cf -- *character formatted content architecture*
cfp -- *character formatted processable content architecture*
cp -- *character processable content architecture*
gfp -- *geometric graphics formatted processable content architecture*
rf -- *raster graphics formatted content architecture*
rfp -- *raster graphics formatted processable content architecture*

E.2.2.4 Data element type names

The ODL names for data element types are the same as the ODL names for the content architecture classes. All are permitted in the logical structure; those with “formatted” in the name are also permitted in the layout structure.

E.2.2.5 Data content notation names

In ODL, content architectures are represented by an SGML construct called a “data content notation”. It is necessary to declare each notation that is used in a document (see E.10).

An ODL notation name is constructed by prefixing “**ODA**” to the ODL content architecture class name. To allow for future changes in ODA, the prefix “**ODA**” in notation names and parameter entity names is reserved.

E.2.2.6 SGML generic identifier (GI)

An element’s generic identifier is normally derived from the ODA user-visible name for an object class description.

NOTE – The word “derived” is used to denote that normal SGML rules must be followed. This means that the generic identifier must be a unique name for its class and it must conform to the concrete syntax. If the user-visible name satisfies these requirements then it can be used as specified. If not, then some implementation-specific derivation must be accomplished to satisfy the SGML rules. This will not affect processing since the GIs carry no semantics and are used merely to establish linkage. If the user-visible name must be preserved for other purposes, an SGML comment and convention can be used. For example “<!-- UVN: *user-visible name* -->” where “**UVN:**” is the convention.

Where no object class description exists (for example, when there is no generic part), the ODL name for the object type (see E.2.2.1 and E.2.2.2) is used instead.

A generic identifier cannot be the same as an ODL object type name, unless the element is of that object type and no other elements are of that object type. In the layout structure, such elements must have a fixed object type attribute whose value is the object type name.

A generic identifier cannot be the same as an ODL data element type (content architecture class) name, unless the element is a data element of that type (see E.2.2.4).

A generic identifier cannot be “**null**”, in any combination of uppercase and/or lowercase characters.

E.2.2.7 SGML unique identifier (ID)

In ODL, an object identifier is represented symbolically by an SGML construct called a “unique identifier”, or “**ID**”. A symbol is assigned only if there is a need to reference the object.

NOTE – This technique is practical because the attribute “subordinates”, which conceptually requires a reference to every object, is implied in ODL by the position of the subordinate objects.

An ODL unique identifier cannot be “**null**”, in any combination of uppercase and/or lowercase characters.

E.2.2.8 Default value list attribute names

Each default value list that can be specified for an element is represented in ODL by an individual attribute. The attribute names are constructed by prefixing the letters “**dv**” to the ODL name for an object type or content architecture class.

The presently recognized default value list attribute names are:

dvclo	-- <i>composite logical object</i>
dvblo	-- <i>basic logical object</i>
dvpages	-- <i>page set</i>
dvpage	-- <i>page (composite)</i>
dvbpage	-- <i>page (basic)</i>
dvframe	-- <i>frame</i>
dvblock	-- <i>block</i>
dvcf	-- <i>character formatted content architecture</i>
dvcfp	-- <i>character formatted processable content architecture</i>
dvcp	-- <i>character processable content architecture</i>
dvgif	-- <i>geometric graphics formatted processable content architecture</i>
dvrif	-- <i>raster graphics formatted content architecture</i>
dvrifp	-- <i>raster graphics formatted processable content architecture</i>

E.2.3 Content

NOTE – In most SGML applications, the content information (data) of an element with character content normally occurs between its start- and end-tags. The data is either recognized as such because the element’s content is declared to be data and has no markup within it, or because the element has mixed content and the parser distinguishes the data from any nested subelement tags or other markup. In ODL, however, even though nested subelements cannot occur, character content is normally declared to be #PCDATA in order to permit entity references and markup declarations. Geometric and raster graphics content are **NDATA** entities.

The content information attribute of a content portion is represented in ODL as the content of a data element. The other attributes of a content portion are represented as attributes of the data element.

For character content architectures, the data can occur either in the normal content, or in one or more data entities that are referenced from the ODL attribute “**content**” that is defined for the data element. The normal content is declared to be #PCDATA, so that it can contain references to other content portions, and so that the start-tag can be minimized when only one data element type can occur.

Geometric and untiled raster graphics content, which cannot be parsed for markup, is always stored in separate data entities. The entities are referenced by the ODL attribute “**content**” on the data element’s start-tag. Tiled raster graphics content contains one or more data elements, one for each tile, but no tile data. Therefore, tiled raster graphics content can be parsed for markup. Tile content, which cannot be parsed for markup, is always stored in separate data entities. The entities are referenced by the ODL attribute “**content**” on the tile data element’s start-tag.

Generic content is discussed in E.4.2.2.

E.2.4 Linking the logical and layout structures

In order to permit the automatic generation of a specific layout structure, the generic logical structure must be linked to the styles and other attributes that govern the layout process. In ODL, this is accomplished by an explicit **LINKTYPE** declaration. The declaration encompasses other SGML declarations (just as a document type declaration does). In particular, it contains one or more **LINK** set declarations, which associate the ODA logical object class, layout style, presentation style, and layout object class.

NOTE – The following example illustrates two link sets, named “**#INITIAL**” and “**set1**”. Consider the last line, which is the link rule for “**logobj3**” in the link set named “**set1**”. It has four parameters: the logical object class, the layout style directives, the layout object class, and the presentation style attributes. In SGML, they are called the source element type, link attribute specification, result element type, and result attribute specification, respectively.

```

<!LINK #INITIAL
      dlor                                     dlar
      logobj1 [sep="450 00 00"]              #IMPLIED
      logobj2 #USELINK set1 [newlay=page]    #IMPLIED
      logobj3 [blkalign=c]                  layobj2 >
<!LINK set1
      logobj3 [blkalign=l]                  layobj2 [trans=0] >
    
```

The optional **USELINK** parameter in line 4 identifies the link set that will be current for the specified logical object class, except when overridden by the link set associated with a subordinate object. A link set called “**#INITIAL**” must always be present, and is the current link set at the start of the document. In the example, **#INITIAL** is the current link set for all of the logical structure, except within **logobj2** and its subordinates, where **set1** is current.

E.2.5 Attributes

Attribute definitions must be associated with the corresponding element definition (object class description) for all potential attributes of an object. Except, however, that an attribute need not be defined if the attribute is not specified for the object class concerned, or for any object derived from it.

If the attribute definition’s default value is to be overridden for a particular specific object, the attribute must be specified in the start-tag of the element, or in a link or result attribute specification list. Parameter-wise defaulting is achieved by defining entities for each parameter.

NOTE – Conventions for such defaulting can be established by a document application profile.

E.3 Representation of attribute values

The representations of the ODA attributes are presented in the form of SGML public text. In this form they can be referenced from a document rather than included within it.

The semantics of the attribute values are specified in ITU-T Rec. T.412 | ISO/IEC 8613-2. The representation of attribute values is as specified in ITU-T Rec. T.412 | ISO/IEC 8613-2, except where a different representation is specified in the public text or elsewhere in this annex.

The default values specified in the public text are those defined in ITU-T Rec. T.412 | ISO/IEC 8613-2. If a different default value is wanted for an element (such as a non-standard default value specified in the document profile or in an object class description), the public text should not be referenced; instead, the definitions should be duplicated with the required changes made in the default values.

Attribute values are sequences of one or more parameters, separated by SGML separator characters. The description of the attribute in ITU-T Rec. T.412 | ISO/IEC 8613-2 determines the number of parameters, and whether any can be omitted. An omitted parameter is represented by a keyword consisting of two zeros: **00**.

A parameter is either constructed, or is one of a number of primitive types: string, keyword, integer, expression, or identifier. String and expression parameters are delimited, and can contain separator characters. Other parameters are not delimited and cannot contain separator characters.

NOTE – Most attribute values consist of a single parameter.

E.3.1 Constructed parameters

In ITU-T Rec. T.412 | ISO/IEC 8613-2, a parameter is a constructed parameter if one or more of its permissible values is a group of two or more sub-parameters. The description of the attribute in ITU-T Rec. T.412 | ISO/IEC 8613-2 determines the number of sub-parameters, and whether any can be omitted. If more than one sub-parameter is present, they are separated from one another by commas. Successive commas denote an omitted sub-parameter, but they are required only if a succeeding sub-parameter is present.

NOTE – For an example of a constructed parameter, see the attribute “**position**” in the public text.

E.3.2 String parameters

A string parameter could contain characters not permitted in an SGML name token, and it is therefore delimited by SGML **LIT** or **LITA** delimiters.

E.3.3 Keyword parameters

Possible keyword values are defined in ITU-T Rec. T.412 | ISO/IEC 8613-2 for some parameters, and by this annex for others.

Lowercase letters in keyword parameters are treated as though they were uppercase.

For certain parameters whose permissible values constitute a set of keywords, fixed numeric values, or both keywords and fixed numeric values, the value is represented by choosing from a set of substitute keywords. These parameters are documented in comments in the public text, in the form:

parameter name: keyword keyword ...

with the keywords appearing in the same order as the permissible values that they represent appear within ITU-T Rec. T.412 | ISO/IEC 8613-2. For attributes that have but one parameter, the attribute name is the parameter name.

NOTE – For example:

-- *side of sheet: R V U* --

means that in the “side of sheet” parameter of the attribute “medium type”, a value of “**r**” represents ‘recto’, a value of “**v**” represents ‘verso’, and so on.

E.3.4 Integer parameters

An integer is represented by a sequence of digits. If preceded by a hyphen, it represents a negative integer.

Parameters whose permissible values constitute an enumerated set of quantities of degrees or SMUs are represented by the integer quantities alone, without the word “degrees” or “SMU”.

E.3.5 Real parameters

A real number is represented as defined for the value notation of ASN.1 in CCITT Rec. X.208 | ISO/IEC 8824.

NOTE – A value without a fractional part will be regarded as an integer.

E.3.6 Expression parameters

Expression parameters use the ODA human-readable expression notation defined in normative Annex A of ITU-T Rec. T.412 | ISO/IEC 8613-2. Its application to ODL is specified in this subclause.

NOTE – Construction expressions are discussed in E.4.2.1.

E.3.6.1 Delimiters

The hexadecimal form of a string literal is represented in functional notation to minimize potential conflicts with SGML delimiters:

H(hexadecimal string)

ISO/CEI 8613-5 : 1994 (S)

NOTE – When the reference delimiter set is used, attribute values containing ODA string expressions should normally be delimited with **LITA** delimiters, as the ODA expression notation uses **LIT** delimiters for string literals.

E.3.6.2 Names and identifiers

An object class identifier is represented by the ODL generic identifier (element type).

An object type is represented by its ODL name.

NOTE 1 – ODL naming rules prevent conflicts between GIs and ODL object type names.

An object identifier is represented by an SGML unique identifier.

NOTE 2 – An element must have an **ID** attribute specified on its start-tag in order for there to be an object identifier to reference.

A binding name is represented by an SGML name derived from it.

NOTE 3 – It cannot be confused with any other ODL name because it can only occur as the second argument of a binding reference.

E.3.6.3 String literals

A string literal in an expression parameter may be contained in a general entity that is referenced from the expression by means of an ODL function called “**E**”:

E(general entity name)

NOTE – The **E** function may be used for string literals that contain non-SGML characters.

E.3.7 Parameters requiring names or identifiers

Object types, object class identifiers, and object identifiers, are represented as specified in E.3.6.2.

When a unique identifier occurs in a context in which a generic identifier or object type name could also occur, the unique identifier is represented as the argument to an “**ID**” function to distinguish it.

Example – ID(myid)

A null name or identifier is represented by the keyword “**null**”.

E.3.8 Special SGML constructs

Some ODA attributes are represented by SGML constructs other than the SGML attribute syntax. Their representation is described for each such attribute individually.

E.3.9 Alternative descriptions

Alternative descriptions are represented in ODL using marked sections. For this purpose, a primary subtree and each of its alternative subtrees are each enclosed in a marked section and are placed in the document in the order of decreasing preference. A document is interchanged with the primary subtree marked **INCLUDED** and the alternative subtrees marked **IGNORED**. This may be changed by the recipient if required. To facilitate ignoring primary descriptions and including alternative descriptions, conventional use of entities allows for avoiding having to change the external keywords. The names of the entities to choose an appropriate alternative can be derived from the attribute “**switch**” in the “alternative feature set” in the document profile.

E.3.10 Protected parts

E.3.10.1 Enciphered parts

In ODL a single enciphered part is always contained in an entity that contains only that enciphered part. An enciphered part identifier is represented in ODL by the entity name of the entity containing the enciphered part.

The particular kind of enciphered part description is determined unambiguously by the content in which the enciphered part ID occurs.

NOTE – A user may wish to identify the particular kind of enciphered part description by placing a comment in the entity declarations for the enciphered part entity.

E.3.10.2 Sealed parts

A sealed document body part has its normal (not enciphered) structure. A sealed document body part is identified by the presence of the attribute “sealed” (see E.4.5.6.2) on the element.

A sealed document profile is represented by a list of the names of the document profile attributes that are sealed. This list is the value of the ODL attribute “**sealatts**” of a **sealedpr** element.

NOTES

1 Preservation of constituents and content seals is possible only if a normalized encoding of the sealed constituents and content is produced. This makes authentication encoding dependent, i.e. the encoding of sealed constituents and content can not be modified in any manner without invalidating seals and losing authentication. This further means that the original encoding of a sealed constituent or content portion, either ASN.1 binary or ODL character encoding, must be preserved.

2 As it is customary for SGML applications to preserve the SGML forms, in this case the ODL form, of the encoded document, no additional rules for preserving the authenticity of sealed document parts are required. The authenticity is preserved by transmitting the original SGML form of the sealed document parts to the intended recipient(s). It is possible to facilitate the processing of sealed documents by placing the sealed document parts in entities.

E.4 Shared attributes

E.4.1 Identification attributes

E.4.1.1 Object type

E.4.1.1.1 Logical objects

The attribute “object type” is not specified for logical objects, as it is implied by the content model:

- a) if the content is declared to be a data element or a choice of data elements, the object is a basic logical object;
- b) if the element is the document element, the object is the document logical root;
- c) in all other cases, the object is a composite logical object.

E.4.1.1.2 Layout objects

The attribute “object type” is declared as follows:

objtype NAME #FIXED ODLname

where “**ODLname**” is the ODL name for the object type, as described above.

NOTE – The attribute “object type” must be defined for a layout object class even if the object type name is used as its generic identifier.

E.4.1.2 Object identifier

The attribute “object identifier” is represented symbolically by an SGML “unique identifier” attribute, as follows:

id ID #IMPLIED

It need be defined and specified only for elements that are actually referenced.

E.4.1.3 Object class identifier

The attribute “object class identifier” is the “element type” in an element definition.

E.4.2 Construction attributes

E.4.2.1 Generator for subordinates

The semantics of the attribute “generator for subordinates” are represented in ODL by the SGML content model syntax.

NOTE – The content model syntax differs only in notational constructs from the human-readable construction expression in Annex A of ITU-T Rec. T.412 | ISO/IEC 8613-2.

An ambiguous generator for subordinates must be made unambiguous by means of “intermediate elements”, as described in ISO 8879. An intermediate element has no semantic effect. It is distinguished from other elements in the following manner:

- 1) In the logical DTD, the following attribute is defined for it:
ignore NAME #FIXED ignore
- 2) In the layout DTD, the attribute “object type” is defined for it as follows:
objtype NAME #FIXED ignore

E.4.2.2 Content generator and generic content information

E.4.2.2.1 Layout structure

In the layout structure, the attribute “content generator” is declared for data elements as follows:

congen CDATA #FIXED ‘string expression’

and the attribute “content information” is declared as:

coninfo ENTITIES #FIXED ‘entity names’

E.4.2.2.2 Link attribute definition

In a link attribute definition, the attribute “content generator” is declared as follows:

congen CDATA ‘string expression’

The attribute “content information” is not declared as such; instead, its value is assigned to the attribute “**congen**”, and the ODL attribute “**gentype**” is set to “**CONINFO**” to indicate this. The latter attribute is declared as:

gentype NAME "CONGEN"

If the attribute “content generator” is specified at the same time, it is specified as the value of the ODL attribute “ignored content generator”:

icongen CDATA #IMPLIED

The ODL attribute “**congen**” can have semantic significance only when the instance of the source data element has no data and the ODL attribute “**content**” is not specified. In such cases, the attribute will cause generation of content data for the result data element when the value of the ODL attribute “use content generator” is “**YES**” (the default). To prevent content generation, the attribute “use content generator” should be specified as “**NO**”.

The link attribute “use content generator” is declared as:

ucongen CDATA yes

E.4.3 Relationship attributes

E.4.3.1 Object class

The attribute “object class” is an element’s generic identifier, which is specified on its tags.

E.4.3.2 Subordinates

The attribute “subordinates” is not specified as such. Elements that occur between the start- and end-tags of another element are that element’s subordinates (sub-elements). The order of appearance of the sub-elements defines the sequential order among them.

E.4.3.3 Content portions

All content portions occur in data elements. Non-character content is always stored in data entities and is referenced by specifying the entity names as the value of a content attribute of the data element, as follows:

content ENTITIES #REQUIRED

Non-character data elements are declared to have **EMPTY** normal content.

For character content, the content portions normally occur between the start- and end-tags of the data element. They are declared to be **#PCDATA** and can contain references to character data entities. The declaration

content ENTITIES #CONREF

allows the data for a given element to occur in separate entities, depending upon whether a value is specified for the attribute. When a content attribute value is specified, the normal content of that instance of the element must be empty.

Generic content is discussed in E.4.2.2.

E.4.3.4 Resource

This attribute is declared as:

resource CDATA #FIXED "table key"

E.4.3.5 Presentation style

See E.8.1.

E.4.4 Content architecture class attributes: content architecture class

The attribute “content architecture class” is declared for data elements as:

conarch NAME #FIXED ODLarch

where “**ODLarch**” is the ODL name for a content architecture class (see E.2.2.3).

NOTE – When an ODA/ODL document is converted to ODIF, the attribute “content architecture class” would be coded in ODIF using either the object identifier representation or the integer representation, as appropriate.

E.4.5 Miscellaneous attributes**E.4.5.1 User-readable comments**

These are represented by SGML comment declarations.

E.4.5.2 Application comments

An application comment is the text of an entity whose name is specified as the value of an attribute that is declared as follows:

apcmnt ENTITY #IMPLIED

E.4.5.3 User-visible name

This attribute is represented either by the element’s generic identifier or unique identifier, or by an associated comment.

NOTE – If the user-visible name contains other than SGML parsable character data, it must appear in a comment.

E.4.5.4 Bindings

Each binding is represented as an SGML attribute that is declared as:

binding-name CDATA #IMPLIED

or

binding-name CDATA 'binding-value'

and specified in the form

binding-name = 'binding-value'

where

“**binding-name**” is an SGML name derived from the ODA binding name; and
 “**binding-value**” is an expression, represented as specified in E.3.6.

E.4.5.5 Default value lists

Default value lists are represented by one or more of the following attributes:

ODLdvnm ENTITY #IMPLIED

where “**ODLdvnm**” is replaced by an ODL name for a default value list (see E.2.2.8).

The value of each attribute is the name of a data entity whose value conforms to the syntax of an attribute specification list.

Default value list attributes can be defined for elements in the source and result document types, and as link attributes. A default value list that is a link attribute must contain a link attribute specification list.

NOTE – In ODL, the attributes “presentation style” and “layout style” are represented as attribute specification lists in link rules (see E.7 and E.8). Default value lists for these attributes consist of similarly-formed attribute specification lists.

E.4.5.6 Security attributes

Security attributes are represented by one or more of the following ODL attributes.

E.4.5.6.1 Enciphered

```

enciph CDATA #IMPLIED -- enciphered --
  -- encsub: (ENCNONE | ENCALL | ENCPART) ENCNONE --
  -- encsubid: sequence of IDREF #IMPLIED --
  -- encppid: ENTITY #IMPLIED --

```

E.4.5.6.2 Sealed

```

sealed CDATA #IMPLIED -- sealed --
  -- sealstat: (SEALED | UNSEALED) UNSEALED --
  -- sealids: sequence of IDREF #IMPLIED --

```

E.5 Layout attributes

E.5.1 Property, formatting, and imaging attributes

This subclause defines a public entity set whose entities contain standard definitions of ODA layout attributes. When the public entity is referenced in a document type definition, the individual entities can be referenced as needed in attribute definition lists.

```

```

E.5.2 Presentation attributes

The presentation attributes are described in the Specifications in ISO/IEC 8613 in which content architectures are specified.

Presentation attributes can be defined and specified only for data elements. The syntactically allowable set of attributes depends on the data element type (that is, on the data element's content architecture class).

Layout presentation attributes are applicable to formatted (**F**) and formatted processable (**FP**) architecture classes. They are known in ODL as "format attributes" and are specified as attributes of a data element in the layout structure.

NOTE – Although they are also syntactically valid in a result attribute specification, they are ignored by the layout process.

Logical presentation attributes are applicable to unformatted processable (**P**) and **FP** architecture classes. They are known in ODL as "format directives" and are specified as link attributes.

ODA also defines "shared" attributes that apply to all three categories of architecture class. They are known in ODL as "format attribute-directives" and are specified for the various content architecture classes as follows:

- a) **P**: result attribute specifications in link rules (that is, in presentation styles).
- b) **F**: like format attributes (that is, in data element start-tags in the layout structure).
- c) **FP**: both of the above, with the link rules being recognized for the layout process and the layout structure start-tags for the imaging process.

When a result attribute must be specified and the layout object class is either a composite layout object or is unspecified, a subordinate link set must be defined. The result attributes are then specified in an entry in the subordinate link set in which the source element type is specified as **#IMPLIED**, and the result element type is the generic identifier of the basic layout object whose content architecture class is that to which the result attributes apply.

NOTE – See how "para" is handled in the example in F.1.2.3.

E.5.3 Colour

E.5.3.1 Colour expressions

A colour expression is represented as **CDATA** and is substructured as follows:

```
-- colour expression: sequence of --
-- colour access mode: DIR IND --
-- choice of --
-- direct colour expression: sequence of --
-- colour specification: (real, real, real [, real]) --
-- colour tolerance: choice of --
-- specified tolerance: sequence of --
-- tolerance value: real --
-- tolerance space: LUV LAB --
-- unspecified tolerance: INFINITE --
-- indexed colour expression: integer --
```

For each element and attribute which has a colour expression as (part of) its value, a referencing attribute must be declared with a value type of **IDREF**. This referencing attribute may be used to identify a colour space for direct colour expressions. In the case of a direct colour expression, any value specified for the referencing attribute must refer to the unique object identifier of a colour space in the profile. When no value for the referencing attribute is present, the default colour space is used. In the case of an indexed colour expression, the colour space is found through the applicable colour table.

E.5.3.2 Colour tables

A colour table is represented as **CDATA** and is substructured as follows:

```
-- colour table: sequence of --
-- colour table entries: sequence of triples of the form --
-- index: integer --
-- colour coordinates: (real, real, real [, real]) --
-- colour tolerance: choice of --
-- unspecified tolerance: INFINITE --
-- specified tolerance: sequence of --
-- tolerance value: real --
-- tolerance space: LUV LAB --
```

For each element and attribute which has a colour table as its value, a referencing attribute must be declared with a value type of **IDREF**. This referencing attribute may be used to identify a colour space for the colour table. Any value specified for the referencing attribute must refer to the unique object identifier of a colour space in the profile. When no value for the referencing attribute is present, the default colour space is used.

E.6 Logical attributes

E.6.1 Protection

The attribute “protection” is defined as:

```
protect NAME unprot -- protection: PROTECT UNPROT --
```

E.6.2 Layout style

See E.7.1.

E.7 Layout style attributes

Layout directive attributes are specified as “link attributes” in the link rule for the logical object class.

E.7.1 Layout style identifier

Layout styles are represented by entities, conventions for which can be defined in a document application profile. The entity name is the layout style identifier. (See the example in F.1.2.3.)

E.7.2 Layout object class

The layout object class attribute is represented by specifying the generic identifier of the layout object class as the result element type in the link rule. If the logical object does not have a known layout object class, the keyword “**#IMPLIED**” should be specified in the link rule instead.

E.7.3 Layout category

A layout category name is represented by an SGML name. In situations where another type of name could also occur, a layout category name is represented as the argument to a “**CAT**” function, to distinguish it.

Example – CAT(mycat)

A layout category name cannot be “**null**”, in any combination of uppercase and/or lowercase characters.

E.7.4 Logical stream category

A logical stream category name is represented by an SGML name. In situations where another type of name could also occur, a logical stream category name is represented as the argument to an “**LCAT**” function, to distinguish it.

Example – LCAT(mylicat)

A logical stream category name cannot be “**null**”, in any combination of uppercase and/or lowercase characters.

E.7.5 Logical stream sub-category

A logical stream sub-category name is represented by an SGML name. In situations where another type of name could also occur, a logical stream sub-category name is represented as the argument to an “LSCAT” function, to distinguish it.

Example – LSCAT(mylscat)

A logical stream sub-category name cannot be “null”, in any combination of uppercase and/or lowercase characters.

E.7.6 Other layout directive attributes

This subclause includes public entities containing attribute definitions for the layout directives. The entities can be referenced directly within an attribute definition list declaration.

E.7.6.1 Layout directives for basic and composite logical objects

```
<! -- Copyright (C) International Organization for Standardization, International Electrotechnical Commission
1994
Permission to copy in any form is granted for use with conforming SGML systems and applications as defined in
ISO 8879, provided this notice is included in all copies.
```

```
-->
```

```
<! -- Public text entity. Typical invocation:
```

```
<!ENTITY % ldir-bc PUBLIC "ISO/IEC 8613-5:1994//TEXT
Layout Directives: Basic and Composite//EN">
```

```
<!ATTLIST clo %ldir-bc; >
```

```
-->
```

```
-- layout object class is not an attribute: see E.7.2 --
-- 'object type page' is represented by 'PAGE' --
indiv CDATA null -- indivisibility --
logcat NAME null -- logical stream category --
logscat NAME null -- logical stream sub-category --
frange CDATA null -- floatability range --
newlay CDATA null -- new layout object --
samelay CDATA null -- same layout object --
synchr CDATA null -- synchronization --
appcmnt ENTITY #IMPLIED -- application comments --
derived NMTOKENS #IMPLIED -- source of derived style --
```

E.7.6.2 Layout directives for basic logical objects

```
<! -- Copyright (C) International Organization for Standardization, International Electrotechnical Commission
1994
Permission to copy in any form is granted for use with conforming SGML systems and applications as defined in
ISO 8879, provided this notice is included in all copies.
```

```
-->
```

```
<! -- Public text entity. Typical invocation:
```

```
<!ENTITY % ldir-b PUBLIC "ISO/IEC 8613-5:1994//TEXT
Layout Directives: Basic//EN">
```

```
<!ATTLIST blo %ldir-b; %ldir-bc;>
```

```
-->
```

```
blkalign NAME r -- block alignment: R L C N --
concat NAME n -- concatenation: C N --
fillord NAME n -- fill order: N R --
category NAME null -- layout category --
offset NUMBERS "0 0 0 0" -- offset: four integers --
sep NUMBERS "0 0 0" -- separation: three integers --
```

E.7.7 Derived layout styles

If a style is derived from another, it shall include the following attribute:

derived = 'link-set-name link-rule-number'

where “link-set-name” is the name of a link set, and “link-rule-number” is a number expressing the position of a link rule within the link set that contains the source of the derived style. (Numbering of link rules within a link set begins at one.)

The attribute “derived from” shall be declared in the same way as other style attributes, as follows:

derived NMTOKENS #IMPLIED -- *source of derived style* --

E.8 Presentation style attributes

E.8.1 Presentation style identifier

Presentation styles are represented by entities, conventions for which can be defined in a document application profile. The entity name is the presentation style identifier. (See the example in F.1.2.3.)

E.8.2 Other presentation style attributes

Layout attributes that have been defined for a result element are syntactically valid as result attributes in link rules. However, only the attributes “border”, “transparency”, and “colour” (see E.5.1) are semantically valid during the layout process, and only when they are attributes of blocks.

E.8.3 Derived presentation styles

Derived presentation styles are represented in the same way as derived layout styles (see E.7.7).

E.9 Content portion attributes

E.9.1 Identification attributes: content identifier

Content (data) is normally identified by the fact that it occurs between the start-tag and end-tag of a data element. The document type specification on the start-tag or tags that introduce the data indicates whether it is part of the logical or layout structure, or both.

When data is stored in a separate entity, its name serves as the content identifier.

E.9.2 Common coding attributes: type of coding

The attribute “type of coding” is defined as an attribute of a data content notation, in the form:

codetype NAME (default)

where the default and permissible values are defined in the Specifications in ISO/IEC 8613 that deal with content architectures, or in document application profiles.

The attribute is specified on the entity declarations of entities containing content portions that conform to the notation.

E.9.3 Content information attributes

E.9.3.1 Content information

The content information attribute is discussed in E.2.3.

E.9.3.2 Alternative representation

The attribute “alternative representation” is defined as follows for data elements whose content portions could have alternative representations:

altreps ENTITIES #IMPLIED

The value of this attribute is a list of names of data entities that contain the alternative representations of the corresponding content portions.

If there is no alternative representation for one or more content portions, the reserved entity name “NONE” should occupy its position in the list. An entity used for an alternative representation cannot be named “NONE”.

E.9.4 Coding attributes

The representation of these attributes is defined in the Specifications in ISO/IEC 8613 that deal with content architectures.

The attributes are defined as attributes of a data content notation, and are specified on the entity declarations of entities containing content portions that conform to the notation.

E.10 Data content notations

E.10.1 Notation declarations for content architectures

ODL notation declarations for data content notations representing the content architecture classes are included in the parts of ISO/IEC 8613 where the content-related attributes are defined.

E.10.2 Content-related public text

The following SGML public text contains notation declarations for existing ODA content architecture classes, element and attribute list declarations for the corresponding data element types, entity declarations for presentation attribute definitions, and entity declarations for lists of data element GIs and default value lists derived from them.

E.10.2.1 Logical structure

E.11 SGML document type declaration and document type definition

E.11.1 Generic and specific parts present

For both logical and layout structures, when either or both generic parts, and at least one corresponding specific part, are present, the usual form of SGML document type declaration is used. The document type name is the generic identifier of the element that represents the root object.

ISO/CEI 8613-5 : 1994 (S)

If there are objects in the specific part that have no object class attribute, the generic part is said to be “partially present”. The ODL object type names of such objects are used as their generic identifiers, and a standard element definition for the object type (see E.11.3) is included in the document type definition.

E.11.2 Generic parts only

When either or both generic parts are present, and no specific parts, a document type declaration in the following form is used:

```
<!DOCTYPE generic [  
  <!ELEMENT generic o o (logical?, layout?)>  
  <!ELEMENT logical - o CDATA>  
  <!ELEMENT layout - o CDATA>  
>
```

E.11.3 Specific parts only

When either or both specific parts are present, and no generic parts, the ODL names for the object types are used as the generic identifiers. One or both of the two following public document type definitions are used, corresponding to the specific parts that are present.

E.11.3.1 Document type definition for specific logical structure

```

```

E.12 Identification of ODA/ODL documents

The application information parameter (“**APPINFO**”) of the SGML declaration must begin with “**ODL**” in order to identify the document as one that conforms to the ODA architecture and is represented in ODL.

E.13 Use of SDIF with ODA/ODL documents

SDIF shall be used for OSI interchange of ODA documents that are represented in ODL. SDIF should be used for non-OSI interchange of such documents.

When SDIF is used, the ODA document profile shall be represented by the first document descriptor in the SDIF data stream, which shall be given the SDIF name “**DOCPROF**”.

E.14 Document profile

This clause specifies a standardized SGML representation of the ODA document profile defined in ITU-T Rec. T.414 | ISO/IEC 8613-4.

NOTE – Some of the elements in the ODA profile are redundant when ODL is used. They are included in order to simplify conversion between ODL and ODIF; the redundant elements can be omitted if desired.

E.14.1 Representation of profile values

E.14.1.1 Attribute list

The profile contains a number of lists of attribute names and their default values. The names are ODL names that are defined for the attributes in other Specifications in ISO/IEC 8613. Such lists are designated in the profile document type definition (DTD) by a reference to the parameter entity “**m.attl**”.

NOTE – The purpose of the attribute lists is to establish default values that differ from those stated in ITU-T Rec. T.410 Series | ISO/IEC 8613.

An attribute list can optionally have an associated scope, such as an object type or content architecture class. The content of an attribute list is in the same form as an SGML attribute specification list.

Multiple non-basic values that may apply to one attribute (and thus cannot be described within one attribute specification list) are represented by using multiple **scope/dvlist** pairs with the same scope.

E.14.1.2 Document reference

The element in the ODL profile representation that contains a reference to a document is termed a “document reference” (**docref**). The element containing the string by which the document described by the profile is referenced is called the “document reference identifier” (**docrefid**). The content of both element types can be an SGML formal public identifier, an ASN.1 object identifier, or a character string.

E.14.1.3 ASN.1 object identifier

A value of an attribute, or content of an element, that is identified in ITU-T Rec. T.414 | ISO/IEC 8613-4 as an “object identifier” is an ASN.1 object identifier. Such a value is represented in the clear text notation that is used for such identifiers in ISO standards. For example, the object identifier for the SDIF abstract syntax would be represented as:

[iso standard 9069 abstract-syntax (1)]

E.14.1.4 Escape sequences

A string parameter that is an escape sequence formulated in accordance with ISO 2022 is represented in the form used for the “public text designating sequence” defined in ISO 8879.

NOTE – This is the clear text form commonly used in ISO standards.

E.14.2 Public text

Anexo F

Ejemplos de representaciones de lenguaje de documento abierto

(Este anexo no es parte integrante de esta Norma Internacional)

This annex is applicable to ISO/IEC 8613-5 only.

This annex illustrates the use of the Open Document Language (ODL) to represent a document and a document profile.

F.1 ODL representation of a document

This clause illustrates the use of ODL to represent the specimen document described in Annex B of ITU-T Rec. T.412 | ISO/IEC 8613-2.

F.1.1 Specific structure examples

An ODL document entity has two parts: a prolog, consisting of markup declarations, and a document instance, representing the specific logical and/or layout structures.

F.1.1.1 Processable form document

In this example, the first declaration (**DOCTYPE**) references the document type definition (DTD) of the logical structure to which the document instance conforms. Within its scope are two entity declarations that allow references to external content portions.

The second document type declaration references the DTD of the layout structure to which the formatted document will conform. There is also a link type declaration that references the link process definition (LPD) for the applicable layout and presentation styles.

```

<!-- Prolog referencing DTD's and LPD, and defining entities -->
<!DOCTYPE letter SYSTEM "Reference to logical structure DTD"
[
  <!-- Entity declarations for specific logical content portions -->
  <!ENTITY diagram SYSTEM "Content portion 3 1 2 0 0" NDATA gfp>
  <!ENTITY signatur SYSTEM "Content portion 3 1 6 0 0" NDATA rfp>
]>
<!DOCTYPE 1 SYSTEM "Reference to layout structure DTD">
<!LINKTYPE ODAlay letter 1[
  <!ENTITY % laylpd SYSTEM "Reference to layout LPD" > %laylpd;
  <!-- Link rule for exceptional paragraph in the body -->
  <!IDLINK ps2 para #USELINK set 4 #IMPLIED>
  <!LINK set4 #IMPLIED %rca; [calign=j cloff=1417 clinespc=400]>
]>
<!-- Document instance representing the specific logical structure -->
<!-- Some markup minimization is used, but more is possible -->
<letter>

</letter>

```

F.1.1.2 Formatted form document

This example illustrates the result of formatting the document represented in F.1.1.1 to produce a document in final formatted form. Note that paragraph “C”, which was a single element in the logical structure, has become two separate blocks in the layout structure.

```

<!DOCTYPE 1 SYSTEM "Reference to layout structure DTD">

</1>

```

F.1.1.3 Formatted processable form document

This example illustrates the result of formatting the document in F.1.1.1 to produce a document in formatted processable form.

The character content data elements differ from those in F.1.1.2 because their content architecture is “cfp” rather than “cf”. This result was achieved by inserting the following entity declaration in the prolog of F.1.1.1:

```
<!ENTITY % rca "cfp" -- Result content architecture: cf cfp -->
```

This example also differs from F.1.1.1 in a number of respects:

- 1) The prolog contains an additional entity declaration, for “%sca”, which modifies the logical DTD and the LPD to specify “cfp” data elements rather than “cp”.
- 2) The document instance includes both the logical and the layout structure. Tags for the logical structure contain the document type specification “(letter)”, tags for the layout structure contain “(1)”, and tags that apply to both structures contain neither.
- 3) The data elements are “cfp” rather than “cp”.
- 4) The generic content portion for “ending” is no longer referenced, as it is not formatted. Instead, formatted text generated by the layout process occurs within the “ending” element.

```

<!-- Prolog referencing DTD's and LPD, and defining entities -->
<!DOCTYPE letter SYSTEM "Reference to logical structure DTD"

F.1.2 Generic structure

This subclause contains the document type definitions and link process definition that were referenced by the specific structure examples.

F.1.2.1 Generic logical structure

This subclause contains the document type definition (DTD) that represents the generic logical structure to which the specific logical structure conforms. The DTD could be included with the document, or (as shown in F.1.1) referenced from a document type declaration.

The entity declaration for “% sca” allows documents conforming to this DTD to contain either processable or formatted processable character content portions.

```
<! -- Document Type Definition for Generic Logical Structure -->
<! -- External reference to declarations for data elements -->
<!ENTITY    % ODAAdlg PUBLIC "ISO/IEC 8613-5:1994//TEXT
      ODA Data Elements: Logical//EN">
      %ODAAdlg;

<! -- Switch, settable in document instance, to choose "cp" or "cfp" -->
<!ENTITY    % sca "cp" -- Source content architecture: cp cfp -->

<! -- Element and attribute declarations for remaining elements -- >
<!ELEMENT   letter    o o  (header, body)>
<!ELEMENT   header    o o  (date, adresse, subject, summary)>
<!ELEMENT   summary   o o  (para+)>
<!ELEMENT   body      - o  ((para | figure)+, ending, sig-name)>
<!ELEMENT   figure     - o  (drawing,caption)>
<!ELEMENT   drawing   o o  (gfp)>
<!ELEMENT   ending    - o  (%sca;)>
<!ELEMENT   sig-name   - o  (sig,name)>
<!ELEMENT   sig        o o  (rfp)>
<!ELEMENT   (date | adresse | subject | para | caption | name)
      - o  (%sca;)>
```

F.1.2.2 Generic layout structure

This subclause contains the document type definition (DTD) that represents the generic layout structure to which the formatted document generated by the layout process conforms. The DTD could be included with the processable form document, or (as shown in F.1.1) referenced from a document type declaration.

```
<! -- Document Type Definition for Generic Layout Structure -->
<! -- External reference to declarations for data elements -->
```

```

<!ENTITY % ODAcly PUBLIC "ISO/IEC 8613-5:1994//TEXT
          ODA Data Elements: Layout//EN">

Anexo G

Utilización del tipo codificación distinguida o canónica

(Este anexo no es parte integrante de esta Norma Internacional)

G.1 El problema a resolver

Las reglas de codificación distinguida y canónica están pensadas para ayudar en la provisión de mecanismos que aseguran la integridad utilizando autenticadores del material a transferir.

El concepto de autenticador está suficientemente claro, e implica tomar el patrón de bits a transferir, aplicarle a alguna forma de función de desmenuzamiento para reducirlo a unos cuantos octetos, encriptar estos octetos para autenticar el autenticador y transmitir a continuación el autenticador con el material original (que se envía en claro). A su recepción, se calcula de nuevo el autenticador a partir del texto claro recibido y se compara con el autenticador recibido. Si son iguales, el texto no ha sido manipulado; en caso contrario sí.

Este simple concepto resulta más difícil cuando se utiliza el modelo ISO y, en particular, la capa de presentación.

Aparecen dos problemas, el primero de los cuales es una cuestión de modelación y de la denominada independencia de capas; el segundo se refiere al empleo de relevos de capas de aplicación, tal como se utilizan en las Recomendaciones de la serie UIT-T X.400 | ISO/CEI 10021.

En el tema de la modelación, la función de desmenuzamiento y el algoritmo de encriptación forman parte de la operación de aplicación, pero la aplicación no conoce ni controla la codificación real que utilizará la capa de presentación. Análogamente en la recepción, la decodificación y por tanto la destrucción de la cadena de bits, es una cuestión de la capa de presentación. Se han propuesto tres soluciones a este problema:

- a) desechar el empleo de los octetos reales producidos por la capa de presentación para uso en el autenticador (los expertos en presentación y ULA han adoptado el criterio actual);
- b) poner los mecanismos de desmenuzamiento y del autenticador en la propia capa de presentación (esta solución fue rechazada como parte de la amplia cuestión de poner el soporte para la encriptación en ASN.1; en el momento del rechazo se arguyó que el trabajo sobre seguridad no estaba maduro, y que no se quería prejuzgar el posible resultado);
- c) modelar una interconexión compleja con la capa de presentación en donde, en transmisión, se presenta un valor para codificación, se produce la codificación y se devuelve a la capa de aplicación que calcula el autenticador, y a continuación se transmite el conjunto; en recepción, además de producir el valor abstracto, las codificaciones recibidas se pasan a la capa de aplicación para verificar el autenticador (este modelo fue rechazado por el grupo ULA);
- d) efectuar la codificación en su totalidad en la capa de aplicación, sin utilizar los servicios de presentación para negociar la sintaxis de transferencia (en realidad esto es un rechazo del modelo de referencia OSI, y no sería aceptable como solución generalizada).

Podrá argüirse que la falta de acuerdo sobre un modelo para describir un proceso aparentemente sencillo y practicable (producción de la codificación y a continuación del autenticador y transmisión de ambos, comprobación con respecto al autenticador en la recepción) no es algo que deba aceptarse como una posición a largo plazo. Tal observación tendría mucha validez si no fuera por el segundo problema de los relevos de aplicación y si no hubiera otras soluciones practicables. (En este documento se indica una solución alternativa que se utiliza en la Rec. UIT-T X.509 | ISO/CEI 9594-8 y que se considera viable y libre de los problemas de modelación y de los sistemas de relevo.)

El segundo problema consiste en que, si está presente un relevo de aplicación, la sintaxis de transferencia utilizada para la segunda transmisión puede diferir de la acordada para la primera (por ejemplo, el uso de reglas de codificación por paquetes en una de ellas y reglas de codificación básica en la otra). Esto derrotaría al autenticador, a menos que se abriera éste y se recalculara en el relevo, lo que implicaría intercambios de seguridad en el relevo, siendo así que lo que se requiere es seguridad de extremo a extremo.

NOTA – Ha habido sugerencias de que podría desearse transmitir un contexto de presentación como «no decodificar/recodificar en los relevos de aplicación», pero esto también plantea problemas de modelación y de otros tipos.

Por eso, estamos obligados a intentar trabajar con un modelo en el que la capa de presentación (junto con cualesquiera relevo de aplicación intermedios) permite la transferencia de la sintaxis abstracta y de la semántica de información, pero no garantiza que la codificación real del patrón de bits (la sintaxis de transferencia) se mantenga de extremo a extremo.

El desafío consiste por tanto en proporcionar un mecanismo autenticador que pueda actuar sobre el tipo de datos abstractos más bien que sobre la cadena de bits transmitida.

El grupo Directorios fue el primero que intentó dar una solución a este problema, y es su modelo el que se describe a continuación.

G.2 Planteamiento para llegar a una solución

El texto que sigue describe primero un modelo conceptual de los que se está haciendo, seguido de una optimización de la implementación, que elimina la doble codificación/decodificación que conlleva el modelo conceptual.

El modelo conceptual funciona como sigue:

- a) El emisor convierte en la capa de aplicación el valor de sintaxis abstracta en una cadena de bits, utilizando las reglas de codificación distinguida o canónica, y genera el autenticador a partir de dicha cadena de bits, que se inserta añadido al valor de la sintaxis abstracta, y ambos valores se transmiten utilizando mecanismos de capa de presentación normales, y cualquier sintaxis de transferencia. Conceptualmente, el emisor codifica dos veces: una para el autenticador (utilizando las reglas de codificación distinguida o canónica) en la capa de aplicación y otra para la transferencia efectiva (utilizando la sintaxis de transferencia negociada) en la capa de presentación.

NOTA – La propiedad importación de la cadena de bits generada por las reglas de codificación distinguida o canónica es que está en correspondencia biunívoca con el valor abstracto. Por eso, la transferencia de extremo a extremo sin pérdida de información al nivel de sintaxis abstracta es equivalente a la transferencia de extremo a extremo de la cadena de bits en la que se basa el autenticador.

- b) El receptor decodificará la cadena de bits recibida en la capa de presentación utilizando la sintaxis de transferencia negociada (que puede diferir de la utilizada por el emisor si está presente un relevo de aplicación), y pasará el valor abstracto a la aplicación. En la capa de aplicación, el valor abstracto se recodifica utilizando las reglas de codificación distinguida o canónica para generar la cadena de bits que ha de autenticarse.

Conceptualmente, por tanto, se codifica dos veces en el extremo emisor y se decodifica una vez y a continuación se codifica en el extremo receptor. Es posible que los implementadores decidan realmente hacerlo así, si el código que soporta la operación de la capa de presentación procede de un suministrador distinto del que produce el código que soporta la aplicación. Por ahora no se sabe la importancia que podría tener esta tara. No obstante, cuando se utilice una realización integrada, existe la posibilidad de la optimización que se describe a continuación. Debe tenerse en cuenta además que las reglas de codificación distinguida y canónica no son más difíciles de aplicar que las reglas de codificación básica, salvo en lo que se refiere a la utilización de **SET OF (JUEGO DE)**. Si tiene que procesarse un gran **SET OF**, es posible que la realización invoque una rutina de clasificación basada en disco. Los diseñadores de aplicaciones deben ser conscientes de esto y tratar de utilizar **SEQUENCE OF (SECUENCIA DE)** en vez de **SET OF** cuando se contemple la utilización de reglas de codificación distinguida o canónica.

G.3 La optimización de la implementación

El modelo y las normas de protocolo OSI especifican el comportamiento requerido, pero en ningún caso pretenden constreñir la arquitectura y la estructura del código real. Por tanto, un implementador puede producir el efecto deseado cualquiera que sea el procedimiento que elija.

Se supone que el empleo de longitud indefinida es más adecuado para un documento ODA, es decir, el uso de las reglas de codificación canónica en lugar de las reglas de codificación distinguida.

En el extremo emisor puede conservarse la cadena de bits producida (conceptualmente en la capa de aplicación) y utilizarse para proporcionar la codificación efectuada conceptualmente en la capa de presentación. Esto es adecuado en emisión si la sintaxis de transferencia negociada son las reglas de codificación básica ASN.1 o las reglas de codificación distinguida ASN.1. Si no fueran ni unas ni otras, es necesaria codificación doble.

Análogamente, en extremo receptor, puede conservarse la cadena de bits (para cualquier sintaxis de transferencia), y la implementación puede utilizarla para comprobar el autenticador. Si hay concordancia, se acaba el problema, y si no la hay puede tratarse de un problema de sintaxis de transferencia, siendo necesario recodificar desde el valor abstracto para determinar si hubo manipulación o no.

Para hacer máximas las posibilidades de no tener que duplicar la codificación/decodificación, sería conveniente que los sistemas que utilicen este mecanismo trataran de negociar una sintaxis de transferencia de reglas de codificación canónica (o distinguida) (utilizando el identificador de objeto ASN.1 adecuado) como su primera preferencia, y recurrieran a las reglas de codificación básica (primera preferencia), o a paquetes de reglas o algunas otras reglas de codificación como segunda referencia.
