# Recommendation ITU-T Z.100

## Specification and Description Language – Overview of SDL-2010

### Annex F2

#### SDL-2010 formal definition: Static semantics

#### Summary

Annex F2 describes the static semantic constraints of SDL-2010, the mapping to the abstract grammar and the transformations identified by the 'Model' clauses of Recommendations ITU-T Z.101, Z.102, Z.103, Z.104, Z.105 and Z.107, that are included by reference in Recommendation ITU-T Z.100.

#### History

Edition	Recommendation	Approval	Study Group	Unique ID*
1.0	ITU-T Z.100	1984-10-19		<a href="http://handle.itu.int/11.1002/1000/2222">11.1002/1000/2222</a>
1.1	ITU-T Z.100 Annex A	1984-10-19		<a href="http://handle.itu.int/11.1002/1000/6664">11.1002/1000/6664</a>

## Keywords

Formal definition, SDL-2010, shorthand transformations Static semantics, specification and description language.

## FOREWORD

The International Telecommunication Union (ITU) is the United Nations specialized agency in the field of telecommunications, information and communication technologies (ICTs). The ITU Telecommunication Standardization Sector (ITU-T) is a permanent organ of ITU. ITU-T is responsible for studying technical, operating and tariff questions and issuing Recommendations on them with a view to standardizing telecommunications on a worldwide basis.

The World Telecommunication Standardization Assembly (WTSA), which meets every four years, establishes the topics for study by the ITU-T study groups which, in turn, produce Recommendations on these topics.

The approval of ITU-T Recommendations is covered by the procedure laid down in WTSA Resolution 1.

In some areas of information technology which fall within ITU-T's purview, the necessary standards are prepared on a collaborative basis with ISO and IEC.

## NOTE

In this Recommendation, the expression "Administration" is used for conciseness to indicate both a telecommunication administration and a recognized operating agency.

Compliance with this Recommendation is voluntary. However, the Recommendation may contain certain mandatory provisions (to ensure, e.g., interoperability or applicability) and compliance with the Recommendation is achieved when all of these mandatory provisions are met. The words "shall" or some other obligatory language such as "must" and the negative equivalents are used to express requirements. The use of such words does not suggest that compliance with the Recommendation is required of any party.

## INTELLECTUAL PROPERTY RIGHTS

ITU draws attention to the possibility that the practice or implementation of this Recommendation may involve the use of a claimed Intellectual Property Right. ITU takes no position concerning the evidence, validity or applicability of claimed Intellectual Property Rights, whether asserted by ITU members or others outside of the Recommendation development process.

As of the date of approval of this Recommendation, ITU had not received notice of intellectual property, protected by patents/software copyrights, which may be required to implement this Recommendation. However, implementers are cautioned that this may not represent the latest information and are therefore strongly urged to consult the appropriate ITU-T databases available via the ITU-T website at <http://www.itu.int/ITU-T/ipr/>.

# Recommendation ITU-T Z.100

## Specification and Description Language – Overview of SDL-2010

### Annex F2

#### SDL-2010 formal definition: Static semantics

##### F2.1 General information for the static semantics

An overview of the static semantics is described in clauses F1.2.1, F1.2.2 and F1.2.3 of Annex F1.

##### F2.1.1 Definitions used from Annex F1

The following definitions for the syntax and semantics of abstract state machines (ASM) are used within this annex (Annex F2). They are defined in Annex F1. They are introduced here for cross-referencing reasons together with the keyword **provided** that is used in transformation rules (see clause F2.2.1.4 Transformation rules).

The keywords **case**, **choose**, **controlled**, **else**, **elseif**, **endcase**, **endchoose**, **endif**, **endlet**, **if**, **initially**, **let**, **monitored**, **of**, **otherwise**, **provided**, **then**.

The domains *X*, *BOOLEAN*, *NAT*, *TOKEN*, *DefinitionAS1* and *DefinitionAS0*.

The functions *chr*, *empty*, *false*, *head*, *isAncestorAS0*, *isAncestorAS1*, *isSameNode0*, *last*, *length*, *num*, *parentAS0*, *parentAS0ofKind*, *parentAS1*, *parentAS1ofKind*, *replaceInSyntaxTree0*, *replaceOnceInSyntaxTree0*, *substring*, *tail*, *take*, *toSet*, *true* and *undefined*.

The operation symbols  $*$ ,  $+$ , **-set**, **-seq**,  $=$ ,  $\neq$ ,  $\wedge$ ,  $\vee$ ,  $\Rightarrow$ ,  $\Leftrightarrow$ ,  $\neg$ ,  $\exists$ ,  $\forall$ ,  $>$ ,  $\geq$ ,  $<$ ,  $\leq$ ,  $+$ ,  $-$ ,  $*$ ,  $/$ , **in**,  $\times$ ,  $\hat{\phantom{x}}$ ,  $\cup$ ,  $\cap$ ,  $\setminus$ ,  $\in$ ,  $\notin$ ,  $\subseteq$ ,  $\subset$ ,  $||$ , **U**,  $\emptyset$ , **mk-**, **s-**, **s1-**, **s2-**.

For more information about the syntax of ASM see Annex F1.

The domain *TOKEN* is used in the definition of the AS0 constructors for  $\langle \text{name} \rangle$ ,  $\langle \text{quoted operation name} \rangle$ ,  $\langle \text{character string} \rangle$ ,  $\langle \text{hex string} \rangle$ ,  $\langle \text{bit string} \rangle$  and the AS1 constructor *Name*. In the formal definition it is assumed the unique *TOKEN* element values can be represented by character strings such as "Predefined", so that the  $\langle \text{name} \rangle$  for the predefined package is **mk-** $\langle \text{name} \rangle$ ("Predefined") and the *Name* for the predefined package is **mk-***Name*("Predefined"). In most cases, the *TOKEN* element value is the same for the  $\langle \text{name} \rangle$  and the corresponding *Name*. The construct  $\langle \text{name} \rangle(x)$  is a  $\langle \text{name} \rangle$  where  $\langle \text{name} \rangle.s\text{-}i\text{-}TOKEN$  is represented by the sequence of characters for the actual name *x*: letters or digits or underlines for  $\langle \text{name} \rangle$  in clause 6.1 of [ITU-T Z.101]; decimal digits for  $\langle \text{integer name} \rangle$  in clause 6.1 of [ITU-T Z.101]; decimal digits or  $\langle \text{full stop} \rangle$  or e or E or  $\langle \text{hyphen} \rangle$  or  $\langle \text{plus sign} \rangle$  for  $\langle \text{real name} \rangle$  in clause 6.1 of [ITU-T Z.101]; and for a  $\langle \text{string name} \rangle$  ( $\langle \text{character string} \rangle$ ,  $\langle \text{hex string} \rangle$  and  $\langle \text{bit string} \rangle$  in clause 6.1 of [ITU-T Z.101]) the sequence of characters specified including enclosing and enclosed apostrophes. One case where the *TOKEN* value is not the same for the  $\langle \text{name} \rangle$  and the corresponding *Name* is for operator names (including literal and quoted operation names) where the *TOKEN* value for the *Name* depends on the signature of the operation and data type in which it is defined (see clause F2.2.9.5 Operations below).

##### F2.1.3 Status of Annex F2 (this annex)

There have been a significant number of changes since the (11/2018) edition. No known issues remain unresolved for full alignment with the text of SDL-2010 in the main body of [ITU-T Z.100], [ITU-T Z.101], [ITU-T Z.102], [ITU-T Z.103], [ITU-T Z.104], [ITU-T Z.105], [ITU-T Z.106], and [ITU-T Z.107]. There are a few functions at the end of the Recommendation that do not have formally specified bodies.

## F2.2 Static semantics

In this annex, the static semantics of SDL-2010 is formalized. This entails defining static well-formedness rules for the concrete and abstract syntax, transformations of the concrete syntax and mappings from concrete to abstract syntax. The concrete syntax is expressed using Abstract Syntax Notation level 0 (AS0), an abstraction of the SDL text-only phrase representation (SDL-PR) grammar (see [ITU-T Z.106]). The well-formedness rules are expressed in terms of first order predicate calculus. The transformations are represented as rewrite rules, comprising patterns, conditions (expressed using first order predicate calculus) and substitutions. The mappings are expressed using the abstract state machine formalism defined in Annex F1.

For the static semantics, the presentation of the grammar as described in Annex F1 is again used.

Context conditions (well-formedness rules) are reflected in the abstract syntax tree as relations from nodes to nodes. First order predicate calculus is used to express the relations as follows: The nodes of the AST are the objects of reasoning. Some functions are defined to retrieve nodes, e.g., the function *n.parentAS1* returns the parent node of *n*. This is explained in detail in Annex F1. Syntax structures are described on sets of nodes by quantifying over them. Predicates are defined over nodes showing the context-dependent rules of these nodes.

For example, in order to define that all the entities of the same type in a scope unit obey the rules of no duplicate appearance, the following static semantic rule is defined:

$$\forall d, d1 \in ENTITYDEFINITION1: d.entityKind1 = d1.entityKind1 \wedge d \neq d1 \Rightarrow d.identifier1 \neq d1.identifier1$$

where:

*d* and *d1* represent any two abstract syntax tree nodes belonging to the set *ENTITYDEFINITION1*.

*d.entityKind1* and *d1.entityKind1* get the entity kinds of the corresponding syntax constructs.

*d.identifier1* and *d1.identifier1* get the full identifiers of the corresponding syntax constructs.

### F2.2.1 General definitions

#### F2.2.1.1 Division of text

The static semantics is presented with the following division of text. Please find below the headings used and for each of the headings a short description of the contents.

##### **Abstract syntax**

This part is used to describe the abstract grammar as already defined within [ITU-T Z.100]. There will be usually no comments in this section as it is copied as is from the language definition.

##### **Conditions on abstract syntax**

This part reflects the conditions that can be formulated on the abstract syntax level. The conditions are usually commented by the corresponding part of the language definition.

##### **Concrete syntax**

This part shows the concrete syntax. In fact, an abstraction of the concrete syntax, namely the AS0 as defined below, is used. There will be usually no comments in this section as it is copied from the language definition.

##### **Conditions on concrete syntax**

This part reflects the conditions that have to be true for the concrete syntax (AS0 here). The conditions are usually commented by the corresponding part of the language definition.

## Transformations

This part shows the transformations within the AS0. Please see below for the format of the rules. The transformations are usually commented by the corresponding part of the language definition.

### Mapping to abstract syntax

This part shows how the transformed AS0 is mapped to AS1. If the mapping is straightforward, no comments are given.

### Auxiliary functions

This part introduces auxiliary functions that are used later on to define the conditions on AS0 and the transformations. The aim and the definition of the functions are explained.

#### F2.2.1.2 Abstraction of the concrete grammar (AS0)

For the sake of the definition of the static semantics rules, a special format of the concrete grammar is used. This special format is called abstract syntax level 0 (AS0). It is an abstraction of the concrete grammar of the text-only phrase representation (SDL-PR), where all the unnecessary grammar items such as separators and terminal keywords are omitted. Any concrete graphical representation (SDL-GR) graphical constructs in a description are converted to the equivalent SDL-PR: in the conversion annotation (comments, notes and other items such as <create line area> and <gate property area>) and underlines followed by spaces are removed; each text extension is made part of the text it extends; and each multiple page diagram is reduced to one page. Formal rewrite rules for this conversion of SDL-GR graphical constructs to SDL-PR is an issue for further study, but most of the syntax rules of SDL-GR are textual rules that are also part of SDL-PR and therefore require no conversion.

AS0 is in principle generated by a simple parsing algorithm from the concrete grammar of SDL-PR, and the SDL-PR syntax rule names are preserved in AS0. As this algorithm is an item for further study not specified here, the assertion that AS0 is a valid abstraction of SDL-PR is true has been checked by comparing the SDL-PR concrete syntax and AS0.

The AS0 does not only represent the original syntactical structure, but it also forms a tree. To achieve this, the syntax constructors "::<=" of [ITU-T Z.100] are replaced by an alias construct ("=") and a tree node constructor ("::"). Both these constructs are already defined in [ITU-T Z.100] in the scope of the abstract syntax, which is called AS1 here.

The metalanguage for the concrete grammar is defined in [ITU-T Z.111]. However, the notation used in this document to represent semantic subcategories differs from the definition in [ITU-T Z.111]. For example, instead of writing

<data type name>

the following sections will use

<data type<name>

This convention facilitates automatic extraction of the grammar from this document.

#### F2.2.1.3 Static conditions on the concrete syntax (AS0)

Usually, the AS0 conditions are checked before the transformations start. However, some conditions are only valid after some transformation steps. This is indicated by preceding the corresponding condition with a numbering sign (e.g., "=4=>"), where the number in the arrow indicates the next transformation step. This means, a condition with the prefix "=4=>" is checked between the transformation steps 3 and 4. By default, conditions are preceded with "=2=>", i.e., they are checked before any transformations except macro expansion and conversion to AS0.

#### F2.2.1.4 Transformation rules

Transformations and redefinition of functions on AS0 are represented by rewrite rules. The syntax for rewrite rules is:

```
<rewrite rule> ::=
    <pattern> [ <provision> ] "=" [ <integer> ] "=>" <expression> { and <dependent transformation> }*
<dependent transformation> ::=
    <pattern> [ <provision> ] { "=" } <expression>
<provision> ::=
    provided <Boolean<expression>>
```

The pattern (as well as the expression) is written using the syntax for ASM transition rules defined in Part 1 of Annex F.

The pattern can be a sequence, such as " $a = \langle \text{textual typebased agent definition} \rangle$ " in which case the expression is a replacement sequence. The non-terminal constructor names shall all match a non-terminal in the AS0 syntax. A variable is not allowed to appear more than once on the left hand side. Free variable names that appear on the right hand side shall also appear on the left hand side. Furthermore, the pattern and expression patterns shall be correctly typed and be of the same type.

The pattern can be a function, such as "*implicitName*" in which case the expression is a replacement function.

A rule  $Pattern =i=> Expression$  is equivalent to an ASM rule of the form

```
choose  $v:DefinitionAS0$ 
  case  $v$  of
    |  $Pattern$  then
      let  $e = CreateExpr(Expression)$  in
         $replaceInSyntaxTree0(v, e, v.parentAS0)$ 
      endlet
    endcase
  endchoose
```

In the definition above, *CreateExpr* means for every constructor of *Expression* an extend of the corresponding domain and the setting of the contents function to a corresponding **mk-** for the following sub pattern. The placeholder *replaceInSyntaxTree0* means to replace  $v$  by  $e$  in the parent node of  $v$ . This does not cause problems as the syntax tree is a tree and it is always possible to find the parent and to replace one of its children.

A transformation rule can be enclosed in an ASM **let** constructor.

A rule **let**  $e = expression$  **in**  $Pattern =i=> Replacement$  **endlet** is equivalent to an ASM rule of the form

```
let  $e = expression$  in
  choose  $v:DefinitionAS0$  in
    case  $v$  of
      |  $Pattern$  then
        let  $e = CreateExpr(Replacement)$  in
           $replaceInSyntaxTree0(v, e, v.parentAS0)$ 
        endlet
      endcase
    endchoose
  endlet
```

Dependent transformation rules have a similar semantics. They are interpreted together with their main rule for each matching dependent pattern while the provisions of both the main rule and the dependent transformation are met.

A rule **let**  $e = \text{expression}$  **in**  $\text{Pattern} \Rightarrow \text{Replacement}$  **and**  $\text{Pattern1} \Rightarrow \text{Replacement1}$  **endlet** is equivalent to an ASM rule of the form

```

let  $e = \text{expression}$ 
  do in-parallel
    choose  $v:\text{DefinitionAS0}$  in
      case  $v$  of
        |  $\text{Pattern}$  then
          let  $e = \text{CreateExpr}(\text{Replacement})$  in
             $\text{replaceInSyntaxTree0}(v, e, v.\text{parentAS0})$ 
          endlet
        endcase
      endchoose,
      choose  $v:\text{DefinitionAS0}$  in
        case  $v$  of
          |  $\text{Pattern1}$  then
            let  $e = \text{CreateExpr}(\text{Replacement1})$  in
               $\text{replaceInSyntaxTree0}(v, e, v.\text{parentAS0})$ 
            endlet
          endcase
        endchoose
      enddo
    endlet

```

The integer in a rewrite rule means the transformation step this rule belongs to. The steps are described in clause F2.3. In the case of the integer being omitted, the rewrite rule can be applied in any transformation step.

The optional <provisions> of <rewrite rule> are Boolean expressions the <pattern> needs to satisfy for the rule to be applied.

We use one auxiliary function *newName* to construct new names during the transformation.

**monitored** *newName*: <name> → <name>

The constraint on this function is that it always returns a new unique name. However, the result is the same when the argument is the same unless the argument is *undefined*. For an *undefined* parameter a new unique name that is not already used within the syntax tree is provided.

NOTE – *newName* is usually used without an argument, which has the same meaning as *newName(undefined)*.

### F2.2.1.5 Mapping rules

The mapping rules introduce a function.

*Mapping*:  $\text{DefinitionAS0} \rightarrow \text{DefinitionAS1}$

The definition of the function *Mapping* is formed by the concatenation of all the cases contained in all **Mapping** sections. This is preceded with the following header part and followed by an **endcase**.

*Mapping*( $a:\text{DefinitionAS0}$ ):  $\text{DefinitionAS1} =_{\text{def}}$   
**case**  $a$  **of**

This way the mapping function is defined step by step in the appropriate places in the **Mapping** sections. Each alternative of the mapping will thus be preceded by a bar ("|"), because it is one alternative of the *Mapping* function description. The bar ("|") is followed by a case selector terminated by the keyword **then** followed by the mapping for that case. Sometimes the *Mapping* function is called with a *DefinitionAS0* parameter that is *undefined*, in which case the result is also *undefined*.

Consider the following as AS0 syntax:

<definition x> :: <y> <zlist>

Typically this would have a *Mapping* starting with the case selector, such as:

| <definition x> (yvalue, zl) **then**

If this *Mapping* were a list of the component mappings, this would be:

| <definition x> (yvalue, zl) **then**  
| < Mapping(yvalue), Mapping(zl) >

Where the zlist value is not used in the mapping, this would be

| <definition x>(yvalue, \*) **then**  
| < Mapping(yvalue) >

Or alternatively (with the same meaning)

| dx = <definition x> **then**  
| < Mapping(dx.s-<y>) >

If the result of mapping has only one component, the list brackets "<" and ">" are optional, so that the mapping of *dx* above could also be defined by:

| dx = <definition x> **then**  
| Mapping(dx.s-<y>)

Where a syntax item is a list, for example in:

<zlist> :: <z>\*

If the result of mapping needs to be a list, this could be (without outermost list brackets):

| <zlist> (zitems) **then**  
| < Mapping(zitems[i] | i ∈ 1.. zitems.length) >

If the result of the mapping needs to be a set, this could be:

| <zlist> (zitems) **then**  
| { Mapping(zitems[i] | i ∈ 1.. zitems.length) }

There is no general rule for the mapping of a list component (such as *zitems*) of a selector (such as <zlist>), so that the mapping has to be given explicitly in each case.

### F2.2.1.6 Predefinition

The following domains and functions are used throughout the static conditions for AS1 and concrete syntax.

#### F2.2.1.6.1 General functions

The function *bigSeq* is used to concatenate a sequence of sequences into one sequence.

*bigSeq*(s: (X\*)<sup>\*</sup>): X\* =<sub>def</sub>  
**if** s = empty **then** empty **else** s.head ^ *bigSeq*(s.tail) **endif**

The function *setToSeq* is used to create a list from a set where each member of the set is an element of the list with no values duplicated in the list. If the set is empty, the list is empty.

*setToSeq*(items: X-set): X\* =<sub>def</sub>  
**if** s = ∅ **then** empty **else**  
  **let** el = items.take **in**  
    < el > ^ *setToSeq*(items \ { el })  
  **endlet**  
**endif**

### F2.2.1.6.2 Domain definitions for AS1

*AGENTKIND1*: the set of agent kinds in AS1.

$AGENTKIND1 =_{\text{def}} \{ \text{system, block, process} \}$

*ENTITYDEFINITION1*: the union of all the entity definitions in AS1.

$ENTITYDEFINITION1 =_{\text{def}}$   
    *Agent-definition*  
     $\cup$  *Agent-type-definition*  
     $\cup$  *Channel-definition*  
     $\cup$  *Composite-state-type-definition*  
     $\cup$  *Data-type-definition*  
     $\cup$  *Gate-definition*  
     $\cup$  *Literal-signature*  
     $\cup$  *Operation-signature*  
     $\cup$  *Parameter*  
     $\cup$  *Procedure-definition*  
     $\cup$  *Signal-definition*  
     $\cup$  *State-node*  
     $\cup$  *Syntype-definition*  
     $\cup$  *Timer-definition*  
     $\cup$  *Variable-definition*  
     $\cup$  *Package-definition*

*ENTITYKIND1*: the set of all the entity kinds in AS1.

$ENTITYKIND1 =_{\text{def}} \{ \text{agent, agent type, channel, exception, gate, literal, operation, package, procedure, signal, sort, state, state type, timer, variable} \}$

*SCOPEUNIT1*: the union of all the scope units in AS1.

$SCOPEUNIT1 =_{\text{def}}$  *Package-definition*  
     $\cup$  *Agent-definition*  
     $\cup$  *Agent-type-definition*  
     $\cup$  *Procedure-definition*  
     $\cup$  *Signal-definition*  
     $\cup$  *Composite-state-type-definition*  
     $\cup$  *Data-type-definition*  
     $\cup$  *State-node*  
     $\cup$  *Compound-node*

$SIGNAL1 =_{\text{def}} \{ id \in Identifier: id.idKind1 \in \{ \text{signal, timer} \} \}$

$TYPEDEFINITION1 =_{\text{def}}$  *Agent-type-definition*  $\cup$  *Procedure-definition*  $\cup$  *Composite-state-type-definition*  $\cup$  *Data-type-definition*

$VALUE1 =_{\text{def}}$  *Literal-signature*

### F2.2.1.6.3 Domain definitions for AS0

$BINDING0 =_{\text{def}}$   $\langle \text{name} \rangle \times ENTITYDEFINITION0$

$BINDINGLIST0 =_{\text{def}}$   $BINDING0^*$

$CONTEXT0 =_{\text{def}}$   $\langle \text{assignment} \rangle \cup \langle \text{decision} \rangle \cup \langle \text{expression} \rangle$

$ENTITYDEFINITION0 =_{\text{def}}$   
     $\langle \text{block definition} \rangle \cup$   
     $\langle \text{channel definition} \rangle \cup$

#### F2.2.1.6.4 Function definitions on AS1

The function *agentInstanceId1* returns the fully qualified *Agent-identifier* of an agent instance set from an *Agent-instance* list.

```
agentInstanceId1(ail: Agent-instance*, pl: Path-item*): Agent-identifier =def
  let sys=take({s ∈ Sdl-specification}) in
  if ail = empty then
    mk-Identifier(mk-Qualifier(empty), sys.s-Agent-definition.s-Agent-name)
  elseif pl = empty then
    agentInstanceId1(ail, mk-Agent-type-qualifier(sys.s-Agent-definition.s-Agent-name))
  elseif ail.length = 1
    mk-Identifier(mk-Qualifier(pl), ail[1].s-Agent-name)
  else
    agentInstanceId1(ail.tail, pl ^ mk-Agent-type-qualifier(ail.head.s-Agent-name))
  endif
endlet
```

The function *agentInstanceSort1* returns the pid sort of the interface defined in the context of the agent that has the same name as the agent. Note that no conversion is needed between the *Agent-identifier* returned by *agentInstanceId1* for the *Sort-reference-identifier* because both these are equivalent to *Identifier*.

```
agentInstanceSort1(aiv: Agent-instance-pid-value): Sort-reference-identifier =def
  agentInstanceId1(aiv.s-Agent-instance-seq, empty)
```

The function *agentKind1* is used to get the agent kind for an *Agent-definition* or *Agent-type-definition*.

```
agentKind1(d: Agent-definition ∪ Agent-type-definition): AGENTKIND1 =def
  if d ∈ Agent-type-definition then d.s-Agent-kind
  else
    let td=getEntityDefinition1(d.s-Agent-type-identifier, agent type) in
      td.s-Agent-kind
    endlet
  endif
endlet
```

The function *decodeResult1* returns the static sort of decoding an expression according to the identified encoding rules. Each of the three elements of *Encoding-rules* is equivalent to *Identifier*; therefore *s3-Identifier* is used to select the *Decode-procedure-identifier* of *er*.

```
decodeResult1(de: Decoding-expression): Sort-reference-identifier =def
  let ep = de.s-Encoding-path in
  let er =
    if ep.s-Encoding-rules = undefined
    then getEntityDefinition1(ep.s-Gate-identifier, gate).s-Encoding-rules
    else ep.s-Encoding-rules
  endif
  in
    getEntityDefinition1(er.s3-Identifier, procedure).s-Result.s-Sort-reference-identifier
  endlet
endlet
```

The function *derivedDataType1* is used to get the data type definition for a given *Syntype-definition*.

```
derivedDataType1(d: Syntype-definition ∪ Data-type-definition): Data-type-definition =def
  if d ∈ Data-type-definition then d
  else getEntityDefinition1(d.s-Parent-sort-identifier, sort).derivedDataType1
```

The function *encodeResult1* returns the static sort of encoding an expression according to the identified encoding rules. Each of the three elements of *Encoding-rules* is equivalent to *Identifier*, therefore *s1-Identifier* is used to select the *Rules-identifier* of *er* and *s2-Identifier* is used to select the *Encode-procedure-identifier* of *er*.

```

encodeResult1(ee: Encoding-expression): Sort-reference-identifier =def
  let ep = ee.s-Encoding-path in
  let er =
    if ep.s-Encoding-rules = undefined
    then getEntityDefinition1(ep.s-Gate-identifier, gate).s-Encoding-rules
    else ep.s-Encoding-rules
    endif
  in
  let nm = getEntityDefinition1(er.s1-Identifier, literal).s-Identifier.s-Name.s-TOKEN in
  case nm of
    | "text" then predefinedId1("Charstring")
    | "BER" then predefinedId1("Octetstring")
    | "CER" then predefinedId1("Octetstring")
    | "DER" then predefinedId1("Octetstring")
    | "APER" then predefinedId1("Octetstring")
    | "UPER" then predefinedId1("Bitstring")
    | "CAPER" then predefinedId1("Octetstring")
    | "CUPER" then predefinedId1("Bitstring")

    | "CXER" then predefinedId1("Charstring")
    | "EXER" then predefinedId1("Charstring")
    | "OER" then predefinedId1("Octetstring")
    otherwise
      getEntityDefinition1(er.s2-Identifier, procedure).s-Result.s-Sort-reference-identifier
  endcase
  endlet
endlet
endlet

```

The function *entityKind1* is used to get the entity kind for an entity definition on AS1.

```

entityKind1(d: ENTITYDEFINITION1): ENTITYKIND1 =def
  case d of
    | Agent-definition then agent
    | Agent-type-definition then agent type
    | Channel-definition then channel
    | Composite-state-type-definition then state type
    | Data-type-definition then sort
    | Gate-definition then gate
    | Interface-definition then sort
    | Literal-signature then literal
    | Operation-signature then operation
    | Package-definition then package
    | Parameter then variable
    | Procedure-definition then procedure
    | Signal-definition then signal
    | State-node then state
    | Syntype-definition then sort
    | Timer-definition then timer
    | Variable-definition then variable
    otherwise undefined
  endcase

```

The function *entityName1* is used to get the entity name for an entity definition in AS1.

```

entityName1(d: ENTITYDEFINITION1): Name =def
  case d of
    | Agent-definition then d.s-Agent-name
    | Agent-type-definition then d.s-Agent-type-name
    | Channel-definition then d.s-Channel-name
    | Composite-state-type-definition then d.s-State-type-name
    | Gate-definition then d.s-Gate-name
    | Interface-definition then d.s-Sort

```

```

| Literal-signature then d.s-Literal-name
| Operation-signature then d.s-Operation-name
| Package-definition then d.s-Package-name
| Parameter then d.s-Variable-name
| Procedure-definition then d.s-Procedure-name
| Signal-definition then d.s-Signal-name
| State-node then d.s-State-name
| Syntype-definition then d.s-Syntype-name
| Timer-definition then d.s-Timer-name
| Value-data-type-definition then d.s-Sort
| Variable-definition then d.s-Variable-name
otherwise undefined
endcase

```

The function *fullQualifier1* is used to get the full qualifier for an entity definition in AS1.

```

fullQualifier1(d: ENTITYDEFINITION1): Qualifier =def
let su = parentAS1ofKind(d, SCOPEUNIT1) in
  if su = undefined then empty
  elseif d.entityKind1 ∈ {operation, literal} ∧ su ∈ Data-type-definition then su.fullQualifier1
  else su.fullQualifier1 mk-Qualifier(su.entityKind1, su.entityName1)
  endif
endlet

```

The function *getEntityDefinition1* gets the entity definition for an identifier and entity kind.

```

getEntityDefinition1(id: Identifier, k: ENTITYKIND1): ENTITYDEFINITION1 =def
  take({d ∈ ENTITYDEFINITION1: d.identifier1 = id ∧ d.entityKind1 = k ∧
    (d.entityKind1 = operation ⇒
      isActualAndFormalParameterMatched1(id.actualParameterListOfOpId1,
        d.formalParameterSortList1))})

```

The function *identifier1* is used to get the identifier with full qualifier for an entity definition in AS1.

```

identifier1(d: ENTITYDEFINITION1): Identifier =def
  mk-Identifier(d.fullQualifier1, d.entityName1)

```

The function *idKind1* is used to return the entity kind for an identifier in AS1 based on syntactic context.

```

idKind1(id: Identifier): ENTITYKIND1 =def
  case id.parentAS1 of
  | Create-request-node ∪ Signal-destination then agent
  | Agent-type-definition ∪ Agent-definition then agent type
  | Procedure-definition ∪ Call-node ∪ Value-returning-call-node then procedure

  | Composite-state-type-definition ∪ State-machine ∪ State-node ∪ State-partition then state type
  | Literal then literal
  | Open-range ∪ Operation-application then operation
  | Input-node then
    if id in id.parentAS1.s-Variable-identifier-seq then variable
    else signal
    endif
  | Variable-access ∪ Assignment then variable
  | Direct-via then

```

```

    if getEntityDefinition1(id, channel) ≠ undefined then channel
    else gate
    endif
endcase

```

The function *isCompatibleTo1* determines if one *Sort-reference-identifier* is compatible to the other.

```

isCompatibleTo1(id1: Sort-reference-identifier, id2: Sort-reference-identifier): BOOLEAN =def
let d1 = getEntityDefinition1(id1, sort) in
let d2 = getEntityDefinition1(id2, sort) in
d1=d2 ∨ isSuperType1(d2, d1)
endlet
endlet

```

The predicate *isSuperType1* is used to determine if the first entity definition is the super type of the second one.

```

isSuperType1(d1: ENTITYDEFINITION1, d2: ENTITYDEFINITION1): BOOLEAN =def
isDirectSuperType1(d1, d2) ∨ ∃ d3 ∈ ENTITYDEFINITION1: isSuperType1(d1, d3) ∧ isSuperType1(d3, d2)

```

The predicate *isDirectSuperType1* is used to determine if the first entity definition is the direct super type of the second one.

```

isDirectSuperType1(d: ENTITYDEFINITION1, d1: ENTITYDEFINITION1): BOOLEAN =def
case d1 of
| Agent-type-definition then
d ∈ Agent-type-definition ∧ d = getEntityDefinition1(d1.s-Agent-type-identifier, agent type)
| Procedure-definition then

| Syntype-definition then
isDirectSuperType1(d, d1.derivedDataType1)
otherwise false
endcase

```

The function *isInOpenRange1* determines if the given value is in the given open range.

```

isInOpenRange1(v1: VALUE1, r: Open-range): BOOLEAN =def
let operator = r.s-Operation-identifier.s-Name in
let vrc = r.s-Constant-expression.value1 in
let v = v1.value1 in
case operator of
| ""="" then v = vrc
| ""/= "" then ¬(v = vrc)
| ""<="" then v ≤ vrc
| "">="" then v ≥ vrc
| ""> "" then v > vrc
| ""< "" then v < vrc
endcase
endlet
endlet

```

The function *predefinedId1* produces the *Identifier* of package *Predefined* with a specified *Name* given as a character string (to represent a *TOKEN*), for example *predefinedId1*("Boolean").

```
predefinedId1(nm: TOKEN): Identifier =def
  qualifiedId1(< mk-Qualifier(< mk-Package-qualifier( mk-Name("Predefined")) >), nm)
```

The function *qualifiedId1* produces the *Identifier* with the specified *Qualifier* and a specified *Name* given as a character string (to represent a *TOKEN*).

```
qualifiedId1(ql: Qualifier, nm: TOKEN): Identifier =def
  mk-Identifier(ql, mk-Name(nm))
```

The function *predefinedLiteral1* produces the *Literal* of package *Predefined* with a specified type and name given as a character strings (to represent *TOKEN* values), for example *predefinedLiteral1* ("Bit", "1").

```
predefinedLiteral1(predefType: TOKEN, litName: TOKEN): Literal =def
  mk-Literal(mk-Identifier(
    < mk-Package-qualifier(mk-Name("Predefined")),
      mk-Data-type-qualifier (mk-Name(predefType)) >, // Qualifier
    mk-Name(litName)))
```

The function *range1* returns the set of elements that satisfy the range condition given as a parameter.

```
range1 (r: Range-condition): VALUE1-set =def
  { v ∈ VALUE1:
    ∃ ci ∈ r.s-Condition-item:
      ((ci ∈ Open-range) ∧ isInRange1(v, ci)) ∨
      ((ci ∈ Closed-range) ∧
        (∃ s1, s2 ∈ ci.s-Open-range: (s1 ≠ s2) ∧ isInRange1(v, s1) ∧ isInRange1(v, s2)))}
```

The function *staticSort1* returns the static sort of *e*.

```
staticSort1(e: Expression ): Sort-reference-identifier =def
  case e of
  | Active-agents-expression then predefinedId1("Natural")
  | Agent-instance-pid-value then agentInstanceSort1(e)

  | <hyphen> then ""-""
  | <concatenation sign> then ""//""
  | <asterisk> then ""*""
  | <solidus> then ""/""
  | mod then ""mod""
  | rem then ""rem""
  endcase
)
```

The function *contextQualifier0* gets the actual <qualifier> specified in an entity definition or a reference. In most cases for an entity definition the <qualifier> in the heading is optional, because the qualifier of the entity identifier is determined by the nearest enclosing scope unit in which the entity definition occurs. The <qualifier> is needed for any <referenced definition> (except outermost packages) if the entity kind with the entity name is ambiguous. It is only allowed to have a <qualifier> in the heading of an entity definition that is a <referenced definition>.

```
contextQualifier0(d: ENTITYDEFINITION0 ∪ REFERENCE0 ): <qualifier> =def
case d of
| <block definition> then d.s-<block heading>.s-<qualifier>
| <block type definition> then d.s-<block type heading>.s-<qualifier>

endif

```

The function *kind0* gets the name of a given entity definition or reference.

```

kind0(d: ENTITYDEFINITION0 ∪ REFERENCE0 ): ENTITYKIND0 =def
case d of
  | REFERENCE0 then d.referenceKind0
  | ENTITYDEFINITION0 then d.entityKind0
endcase

```

The function *name0* gets the name of a given entity or reference.

```

name0(d: ENTITYDEFINITION0 ∪ REFERENCE0 ): <name> =def
case d of
| REFERENCE0 then d.referenceName0
| ENTITYDEFINITION0 then d.entityName0
otherwise undefined
endcase

```

The function *natToIntToken* produces a *TOKEN* corresponding to the given Natural number.

```

natToIntToken(n: NAT): INTOKEN0 =def
case n of
| 0 then "0"
| 1 then "1"
| 2 then "2"
| 3 then "3"
| 4 then "4"
| 5 then "5"
| 6 then "6"
| 7 then "7"
| 8 then "8"
| 9 then "9"
otherwise
  take({t ∈ TOKEN :
    tens ∈ NAT
    ∧ units ∈ NAT ∧ units < 10
    ∧ n = tens * 10 + units
    ∧ t = if tens = 0 then "" else natToIntToken(tens) endif + natToIntToken(units)
  })
endcase

```

The function *intTokenToNat* produces a *NAT* corresponding to the given *INTOKEN0*.

```

intTokenToNat(t: INTOKEN0): NAT =def
  take({n ∈ NAT : natToIntToken(n) = t})

```

The function *predefinedId0* produces the <identifier> of an item of **package** *Predefined* with a specified name given as a character string, for example *predefinedId0*("Charstring").

```

predefinedId0(cs: TOKEN ): <identifier> =def
mk-<identifier>(< mk-<path item>(package, mk-<name>("Predefined"))>, mk-<name>(cs))

```

The function *predefinedItem0* produces an <identifier> for an item defined in a data type of **package** *Predefined* with the specified data type name given as a character string, and the specified item name given as a character string, for example *predefinedItem0*("Boolean", "true").

```

predefinedItem0(q: TOKEN, n: TOKEN): <qualifier> =def
mk-<identifier>(predefinedQual0(q), mk-<name>(n))

```

The function *predefinedQual0* produces a <qualifier> for the context of data type defined in **package** *Predefined* with a specified data type name given as a character string, for example *predefinedQual0*("Integer").

```

predefinedQual0(cs: TOKEN ): <qualifier> =def
< mk-<path item>(package, mk-<name>("Predefined")), mk-<path item>(sort, mk-<name>(cs)) >

```

The function *predefinedSort0* produces a predefined <sort> of **package** *Predefined* with a specified name given as a character string, for example *predefinedSort0* ("Integer").

```

predefinedSort0(cs: TOKEN ): <sort> =def
mk-<sort>(mk-<type expression>(predefinedId0(cs)))

```

The function *predefinedSig0* produces <operation signature> for an operation with name *opn*, predefined argument sorts *argsrts* (given as a list character strings) and predefined result sort *res* (given as a character string) of the data type *sort* (given as a character string) in the package *Predefined*.

```
predefinedSig0(opn: TOKEN, argsrts: TOKEN*, res: TOKEN): <operation signature> =def
mk-<operation signature>(
  undefined, // operation preamble – visibility / virtuality
  mk-<name>(opn),
  mk-<arguments>(< mk-<formal parameter>(part, predefinedSort0(argsrts[n])) : n ∈ 1.. argsrts.length >),
  mk-<result>(predefinedSort0(res))
) // operation signature
```

The function *referenceKind0* gets the entity kind of a specified reference.

```
referenceKind0(ref: REFERENCE0 ): ENTITYKIND0 =def
case ref of
| <block reference> then block
| <block type reference> then block type
| <composite state reference> then state
| <composite state type reference> then state type
| <operation reference> then ref.s-<operation kind>
| <package reference> then package
| <procedure reference> then procedure
| <process reference> then process
| <process type reference> then process type
| <system type reference> then system type
otherwise undefined
endcase
```

The function *referenceName0* gets the name of a given reference.

```
referenceName0(ref: REFERENCE0 ): <name> =def
case ref of
| TYPEREFERENCE0 then ref.s-<identifier>.s-<name>
| <operation reference> then ref.s-<operation heading>.s-<operation name>
otherwise ref.s-<name>
endcase
```

The function *surroundingQualifier0* gets the qualifier to use for entities defined in the surrounding scope unit of a node in AS0.

NOTE – The function *surroundingQualifier0* has the same body as the function *fullQualifier0* but accepts any *DefinitionAS0* item as a parameter, whereas *fullQualifier0* requires an *ENTITYDEFINITION0*.

```
surroundingQualifier0(d: DefinitionAS0): <qualifier> =def
let su = d.surroundingScopeUnit0 in
  if su = undefined then empty
  else su.fullQualifier0^ mk-<path item>(su.entityKind0, su.entityName0)
endlet
```

The function *surroundingScopeUnit0* gets the surrounding scope unit for a node in AS0.

```
surroundingScopeUnit0(d: DefinitionAS0): SCOPEUNIT0 =def
if d ∈ <referenced definition> ^ d.parentAS0 ∈ <sdl specification> then
  parentAS0ofKind(d.referencedBy0, SCOPEUNIT0)
else
  parentAS0ofKind(d, SCOPEUNIT0)
endif
```

## F2.2.2 Visibility rules, names and identifiers

### F2.2.2.1 Name

#### Abstract syntax

<i>Name</i>	::	<i>TOKEN</i>
<i>Agent-name</i>	=	<i>Name</i>
<i>Agent-type-name</i>	=	<i>Name</i>
<i>Channel-name</i>	=	<i>Name</i>
<i>Compound-node-name</i>	=	<i>Name</i>
<i>Connector-name</i>	=	<i>Name</i>
<i>Data-type-name</i>	=	<i>Name</i>
<i>Exception-name</i>	=	<i>Name</i>
<i>Gate-name</i>	=	<i>Name</i>
<i>Interface-name</i>	=	<i>Name</i>
<i>Literal-name</i>	=	<i>Name</i>
<i>Operation-name</i>	=	<i>Name</i>
<i>Package-name</i>	=	<i>Name</i>
<i>Procedure-name</i>	=	<i>Name</i>
<i>Signal-name</i>	=	<i>Name</i>
<i>State-entry-point-name</i>	=	<i>Name</i>
<i>State-exit-point-name</i>	=	<i>Name</i>
<i>State-name</i>	=	<i>Name</i>
<i>State-type-name</i>	=	<i>Name</i>
<i>Syntype-name</i>	=	<i>Name</i>
<i>Timer-name</i>	=	<i>Name</i>

*Variable-name* = *Name*

NOTE 1 – There are no concrete constructs in SDL-2010 for the use of exceptions, but the concept of an *Exception-name* and *Exception-identifier* is retained for descriptions of when an exception is raised. Therefore, an implementation that handles exceptions can extend the formal semantics. Similarly, for the user of the language there is no syntax for an exception name, but <exception name> is defined for the description of predefined data types [ITU-T Z.104] and the exception names are listed as part of **package** *Predefined*.

## Concrete syntax

<name> :: *TOKEN*  
<quoted operation name> :: *TOKEN*  
<character string> :: *TOKEN*  
<hex string> :: *TOKEN*  
<bit string> :: *TOKEN*  
<operation name> = <operator><name> | <quoted operation name>  
<literal name> = <literal><name> | <string name>  
<string name> = <character string> | <bit string> | <hex string>

NOTE 2 – A lexical distinction is made (in clause 6.1 of [ITU-T Z.101]) between a <name>, an <integer name> and a <real name> to avoid some lexical ambiguities, whereas in the static formal semantics these are (currently) all treated as <name>.

## Mapping to abstract syntax

```
| <name>(x) then mk-Name(x)
| <quoted operation name>(x) then mk-Name(x)
| <hex string>(x) then mk-Name(x)
| <bit string>(x) then mk-Name(x)
| <character string>(x) then
  let cscontext = x.parentAS0 in
  case cscontext of
    | <transition option> ∪ <task> ∪ <decision>
      then mk-Informal-text()
    | <textual answer part>
      then
        let q = cscontext.parentAS0.parentAS0.s-<question> in
        if q.s-<operand5>.s-<primary>.s-<literal identifier> ∈ <character string>
          then mk-Informal-text() // after interpretation how the system behaves is undefined
        else
          if (isSubSort0(predefinedId0("Charstring"), q.staticSort0)) ∨
             (length(x) = 1) ∧ (isSubSort0(predefinedId0("Character"), q.staticSort0)) ∨
             (isSubSort0(predefinedId0("NumericString"), q.staticSort0)) ∨
             (isSubSort0(predefinedId0("PrintableString"), q.staticSort0)) ∨
             (isSubSort0(predefinedId0("TeletexString"), q.staticSort0)) ∨
             (isSubSort0(predefinedId0("VideotexString"), q.staticSort0)) ∨
             (isSubSort0(predefinedId0("VisibleString"), q.staticSort0))
            then mk-Name(x)
          else mk-Informal-text() // after interpretation how the system behaves is undefined
        endif
      endif
    endlet
  otherwise mk-Name(x)
  endcase
endlet
```

A <character string> in a <textual answer part> is a special case. If the <question> is informal, all the answers have to be <character string> answers and are informal. If the question is an expression (but not a <character string>) of a sort with values that have a <character string> representation

(as detailed above), a <character string> represents a value of the sort. If the sort of the question expression is not one of these sorts, the <character string> answer is informal.

### F2.2.2.2 Identifier

#### Abstract syntax

<i>Identifier</i>	::	<i>Qualifier Name</i>
<i>Qualifier</i>	=	<i>Path-item*</i>
<i>Agent-identifier</i>	=	<i>Identifier</i>
<i>State-identifier</i>	=	<i>Identifier</i>
<i>Agent-type-identifier</i>	=	<i>Identifier</i>
<i>Procedure-identifier</i>	=	<i>Identifier</i>
<i>Signal-identifier</i>	=	<i>Identifier</i>
<i>Data-type-identifier</i>	=	<i>Identifier</i>
<i>Sort-reference-identifier</i>	=	<i>Sort-identifier</i>   <i>Syntype-identifier</i>
<i>Sort-identifier</i>	=	<i>Identifier</i>
<i>Syntype-identifier</i>	=	<i>Identifier</i>
<i>Timer-identifier</i>	=	<i>Identifier</i>
<i>Gate-identifier</i>	=	<i>Identifier</i>
<i>Exception-identifier</i>	=	<i>Identifier</i>
<i>Composite-state-type-identifier</i>	=	<i>Identifier</i>
<i>Literal-identifier</i>	=	<i>Identifier</i>
<i>Operation-identifier</i>	=	<i>Identifier</i>
<i>Variable-identifier</i>	=	<i>Identifier</i>

#### Conditions on abstract syntax

$$\forall d, d1 \in ENTITYDEFINITION1: d.entityKind1 = d1.entityKind1 \wedge d \neq d1 \Rightarrow d.identifier1 \neq d1.identifier1$$

Each entity of a kind shall have an *Identifier* different from any other entity of the same kind.

NOTE - Consequently, no two definitions in the same scope unit and belonging to the same entity kind are allowed to have the same <name>, except operations defined in the same <data type definition> that differ in at least one argument <sort> or the result <sort> (in which case they have different *Operation-name* values).

#### Concrete syntax

<identifier> :: <qualifier> <name>

<qualifier> = <path item>\*

#### Transformations

$$i = \langle \text{identifier} \rangle \text{ provided } i \neq \text{fullIdentifier0}(i) = 14 \Rightarrow \text{fullIdentifier0}(i)$$

It is allowed to omit some of the leftmost <path item>s, or the whole <qualifier> of an <identifier> if it is possible to uniquely expand the remaining <path item>s to a full <qualifier>. See clause 6.6 of [ITU-T Z.101].

#### Mapping to abstract syntax

$$| \langle \text{identifier} \rangle(q, name) \Rightarrow \text{mk-Identifier}(Mapping(q), Mapping(name))$$

## Auxiliary functions

For any given identifier, return its full identifier.

```
fullIdentifier0(i:<identifier>): <identifier> =def i.refersto0.identifier0
```

For any given identifier, return the definition it refers to.

```
refersto0(i:<identifier>): ENTITYDEFINITION0 =def getEntityDefinition0(i, idKind0(i))
```

For any given entity definition in AS0, the function *identifier0* returns its identifier with full qualifier.

```
identifier0(def: ENTITYDEFINITION0): <identifier> =def  
mk-<identifier>(def.fullQualifier0, def.entityName0)
```

The function *fullQualifier0* is used to get the full qualifier for an entity definition.

```
fullQualifier0(d: ENTITYDEFINITION0): <qualifier> =def  
let su = d.surroundingScopeUnit0 in  
if su = undefined then empty  
else su.fullQualifier0 ^ mk-<path item>(su.entityKind0, su.entityName0)  
endlet
```

The function *fullQualifierWithin0* is used to get the full qualifier for items defined directly within the entity definition *d*.

```
fullQualifierWithin0(d: ENTITYDEFINITION0): <qualifier> =def  
d.fullQualifier0 ^ mk-<path item>(d.entityKind0, d.entityName0)
```

The function *getEntityDefinition0* is used to get the definition that the given identifier refers to.

```
getEntityDefinition0(id:<identifier>, ek: ENTITYKIND0): ENTITYDEFINITION0 =def  
if ek ∈ { operator, literal, method } then  
resolveByContext0(id)  
else  
let su = getStartingScopeUnit0(id, id.surroundingScopeUnit0) in  
if su = undefined then undefined  
else resolveByContainer0(su, id, ek)  
endif  
endlet  
endif
```

The function *resolveByContainer0* binds an <identifier> to a definition through resolution by container.

```
resolveByContainer0(su: SCOPEUNIT0, id:<identifier>, ek: ENTITYKIND0): ENTITYDEFINITION0 =def  
let d1=bindInLocalDefinition0(su, id, ek) in  
if d1 ≠ undefined then d1  
else let d2=bindInBaseType0(su, id, ek) in  
if d2 ≠ undefined then d2  
else let d3=bindInUsedPackage0(su.s-<package use clause>-seq, id, ek) in  
if d3 ≠ undefined then d3  
else let d4=bindInLocalInterface0(su.localInterfaceDefinitionSet0, id, ek) in  
if d4 ≠ undefined then d4  
else let su1=su.surroundingScopeUnit0 in  
if su1 ≠ undefined  
then resolveByContainer0(su1, id, ek)  
elseif ek= system ∧ (∃ sd ∈ <system definition>: sd.s-<name> = id.s-<name> ) then  
take({sd ∈ <system definition>: sd.s-<name> = id.s-<name>})  
elseif ek= package  
∧ id.s-<qualifier> = undefined  
∧ (∃ pd ∈ <package definition>:  
pd.s-<name> = id.s-<name> ∧ pd.s-<qualifier> = undefined)
```

```

    then
        take({pd ∈ <package definition>: pd.s-<name> = id.s-<name>
            ∧ pd.s-<qualifier> = undefined})
    else undefined
    endif endlet // su1
    endif endlet // d4
    endif endlet // d3
    endif endlet // d2
    endif
endlet // d1

```

The function *bindInLocalDefinition0* is used to search in the given scope unit to determine if there exists a local entity definition for the specified identifier.

```

bindInLocalDefinition0(su: SCOPEUNIT0, id: <identifier>, ek: ENTITYKIND0): ENTITYDEFINITION0 =def
    let d = take({d ∈ ENTITYDEFINITION0:
        d.surroundingScopeUnit0 = su ∧ isSameEntityName0(id.s-<name>, d) ∧
        isConsistentKindTo0(d.entityKind0, ek) ∧ isVisibleIn0(d, id.surroundingScopeUnit0)}) in
    if d ≠ undefined then d
    else let rd = take({rd ∈ REFERENCE0 : rd.surroundingScopeUnit0 = su ∧
        rd.referencedDefinition0.entityName0 = id.s-<name> ∧
        isConsistentKindTo0(rd.referencedDefinition0.entityKind0, ek) ∧
        isVisibleIn0(rd, id.surroundingScopeUnit0)}) in
        if rd ≠ undefined then rd.referencedDefinition0
        else undefined
        endif endlet
    endif
endlet

```

The function *bindInBaseType0* finds the entity definition corresponding to the given <identifier> in the base type of the scope unit if there is a specialization and the <identifier> is not within the specialization.

```

bindInBaseType0(su: SCOPEUNIT0, id: <identifier>, ek: ENTITYKIND0): ENTITYDEFINITION0 =def
    let spec = su.specialization0 in
        if (spec = undefined) ∨ isAncestorAS0(spec, id) then undefined
        else resolveByContainer0(spec.s-<type expression>.baseType0, id, ek)
        endif
    endlet

```

The function *bindInUsedPackage0* finds the entity definition corresponding to the given <identifier> in the used packages of the scope unit.

```

bindInUsedPackage0(ucl:<package use clause>*, id: <identifier>, ek: ENTITYKIND0):
    ENTITYDEFINITION0 =def
    if ucl = empty then undefined
    elseif ucl.head = id.parentAS0 then
        bindInUsedPackage0(ucl.tail, id, ek)
    else
        let d = bindInLocalDefinition0(ucl.head.usedPackage0, id, ek) in
            if d ≠ undefined then d
            else bindInUsedPackage0(ucl.tail, id, ek)
            endif
        endlet
    endif
endlet

```

The function *bindInLocalInterface0* finds the entity definition corresponding to the given <identifier> in the interfaces of the scope unit.

```

bindInLocalInterface0(is:<interface definition>-set, id: <identifier>, ek: ENTITYKIND0):
    ENTITYDEFINITION0 =def
    if is = ∅ then undefined

```

```

else
let d = is.take in
let ed = bindInLocalDefinition0(d, id, ek) in
  if ed ≠ undefined then ed
  else bindInLocalInterface0(is \ {d})
endif
endlet // ed
endlet // d
endif

```

The function *isSameEntityName0* is used to determine if the given name has the same name as the entity definition.

```

isSameEntityName0(n: <name>, d: ENTITYDEFINITION0): BOOLEAN=def
(n = d.entityName0)

```

For a given identifier (left most path item may be omitted), the function *getStartingScopeUnit0* gets the starting scope unit denoted by the partial qualifier.

```

getStartingScopeUnit0(id: <identifier>, su: SCOPEUNIT0): SCOPEUNIT0=def
if su = undefined then undefined
elseif isQualifierMatched0(id.s-<qualifier>, su) then su
else let su1 = getStartingSuInUsedPackage0(id, su.usedPackageDefinitionList0) in
  if su1 ≠ undefined then su1
  else let su2 = getStartingSuInInterface0(id, su.localInterfaceDefinitionSet0) in
    if su2 ≠ undefined then su2
    else getStartingScopeUnit0(id, su.surroundingScopeUnit0)
  endif
endlet
endif endlet
endif

```

The function *getStartingSuInUsedPackage0* finds the starting scope unit in the packages list.

```

getStartingSuInUsedPackage0(id: <identifier>, pdl:<package definition>*): SCOPEUNIT0=def
if pdl = empty then undefined
elseif isQualifierMatched0(id.s-<qualifier>, pdl.head) then pdl.head
else getStartingSuInUsedPackage0(id, pdl.tail)
endif

```

The function *getStartingSuInInterface0* finds the starting scope unit in the interface list.

```

getStartingSuInInterface0(id: <identifier>, ifds:<interface definition>-set): SCOPEUNIT0=def
if ifds = ∅ then undefined
else let d = ifds.take in
  if isQualifierMatched0(id.s-<qualifier>, d) then d
  else getStartingSuInInterface0(id, ifds \ {d})
endif endlet
endif

```

The function *isDefinedIn0* determines if an entity definition is defined in a given scope unit.

```

isDefinedIn0(ed: ENTITYDEFINITION0, su: SCOPEUNIT0): BOOLEAN=def
if (su = undefined ∨ ed = undefined) then false
else
  su = ed.surroundingScopeUnit0 ∨
  isVisibleInInterface0(ed, su) ∨
  isVisibleInDataType0(ed, su) ∨
  isVisibleThroughBaseType0(ed, su)
endif

```

The function *isVisibleIn0* determines if an entity definition is visible in a given scope unit.

$isVisibleIn0(ed: ENTITYDEFINITION0, su: SCOPEUNIT0): BOOLEAN =_{def}$   
 $isDefinedIn0(ed, su) \vee$   
 $isVisibleThroughUsedPackage0(ed, su) \vee$   
 $isVisibleIn0(ed, su.surroundingScopeUnit0)$

The function *isVisibleInInterface0* determines if the scope unit contains an <interface definition> that is the defining context of the entity.

$isVisibleInInterface0(ed: ENTITYDEFINITION0, su: SCOPEUNIT0): BOOLEAN =_{def}$   
 $(ed.surroundingScopeUnit0 \in su.localInterfaceDefinitionSet0)$

The function *isVisibleInDataType0* determines if the scope unit contains a <data type definition> which is the defining context of the entity.

$isVisibleInDataType0(ed: ENTITYDEFINITION0, su: SCOPEUNIT0): BOOLEAN =_{def}$   
 $(ed.surroundingScopeUnit0 \in su.localDataTypeDefinitionSet0) \wedge$   
 $(ed \in \langle \text{literal signature} \rangle \cup \langle \text{operation signature} \rangle \Rightarrow ed.isPublic0)$

The function *isVisibleThroughBaseType0* determines if the entity is visible through the base type of the scope unit. The entity is visible if the type is a direct sub type of the base type in which the entity is visible, and the entity is either a literal/operation (that is not private/renamed) or is a formal context parameter of the base type not bound to an actual context parameter.

$isVisibleThroughBaseType0(ed: ENTITYDEFINITION0, su: SCOPEUNIT0): BOOLEAN =_{def}$   
**let**  $spec = su.specialization0$  **in**  
  **if**  $spec = undefined$  **then**  $false$

     $(ed \in \langle \text{literal signature} \rangle \cup \langle \text{operation signature} \rangle \Rightarrow$   
       $\neg isPrivate0(ed) \wedge \neg isRenamedBySpec0(ed, spec)) \vee$   
     $ed \in FORMALCONTEXTPARAMETER0 \Rightarrow \neg isBoundToActualContextPara0(ed, spec))$   
  **endif**  
**endlet**

The function *isVisibleThroughUsedPackage0* determines if an entity definition is visible through used packages.

$isVisibleThroughUsedPackage0(ed: ENTITYDEFINITION0, su: SCOPEUNIT0): BOOLEAN =_{def}$   
**let**  $ucs = su.s-\langle \text{package use clause} \rangle\text{-seq.toSet}$  **in**  
  **if**  $ucs = \emptyset$  **then**  $false$   
  **else**  $(\exists uc \in ucs : ed.surroundingScopeUnit0 = uc.usedPackage0 \wedge$   
     $isVisibleThroughUseClause0(ed, uc))$   
  **endif**  
**endlet**

The function *isBoundToActualContextPara0* determines if a <formal context parameter> is bound to an <actual context parameter> in a <specification>.

$isBoundToActualContextPara0(fcp: FORMALCONTEXTPARAMETER0, spec: \langle \text{specialization} \rangle):$   
 $BOOLEAN =_{def}$   
 $(\exists acp \in \langle \text{actual context parameter} \rangle:$   
   $acp.parentAS0.parentAS0 = spec \wedge isContextParameterCorresponded0(fcp, acp))$

The function *isVisibleThroughUseClause0* determines if an entity definition is visible through the <package public> and <package use clause>.

$isVisibleThroughUseClause0(ed: ENTITYDEFINITION0, uc: \langle \text{package use clause} \rangle): BOOLEAN =_{def}$   
**let**  $pd = uc.usedPackage0$  **in**  
**let**  $pp = pd.s-\langle \text{package heading} \rangle.s-\langle \text{package public} \rangle$  **in**

### F2.2.3 Informal text

#### Abstract syntax

*Informal-text* :: ...

#### Concrete syntax

<informal text> :: <character string>

#### Mapping to abstract syntax

The mapping for informal text is described in clause F2.2.2.1.

### F2.2.4 General framework

#### F2.2.4.1 SDL-2010 specification

#### Abstract syntax

*Sdl-specification* :: [ *Agent-definition* ] *Package-definition-set*

#### Conditions on abstract syntax

$\forall sys \in Sdl-specification :$   
(*sys.s-Agent-definition*  $\neq$  *undefined*  $\Rightarrow$   
( $\exists atype \in Agent-type-definition :$   
(*atype.identifier1* = *sys.s-Agent-type-identifier*  $\wedge$  *atype.s-Agent-kind* = **SYSTEM**)  
) )

The *Agent-definition* (if present) shall have an *Agent-type-identifier* for an *Agent-type-definition* with the *Agent-kind* **SYSTEM**. See clause 7.1 *Abstract grammar* of [ITU-T Z.101].

#### Concrete syntax

<sdl specification> ::  
{ <textual system specification> | <package definition> } <referenced definition>\*  
<textual system specification> ::  
<agent definition>  
| <package use clause>\* <textual typebased agent definition>

#### Transformations

<sdl specification>(sys, r)  
**provided** *sys*  $\in$  (<process definition>  $\cup$  <textual typebased process definition>  $\cup$   
<block definition>  $\cup$  <textual typebased block definition>)  
 $=5\Rightarrow$  **mk**-<sdl specification>( **mk**-<system definition>(empty,  
    **mk**-<system heading>(sys.name0, **mk**-<agent additional heading>(undefined, empty)),  
    **mk**-<agent structure>(undefined, < sys >, **mk**-<agent body>(undefined, empty))),  
r)

A <system specification> being a <process definition> or a <textual typebased process definition> is derived syntax for a <system definition> having the same name as the process, containing implicit channels and containing the <process definition> or <textual typebased process definition> as the only definition. See clause 5.3.1 *Model* of [ITU-T Z.106].

A <system specification> being a <block definition> or a <textual typebased block definition> is derived syntax for a <system definition> having the same name as the block, containing implicit channels and containing the <block definition> or <textual typebased block definition> as the only definition. See clause 5.3.1 *Model* of [ITU-T Z.106].

#### Mapping to abstract syntax

| <sdl specification>(s=<textual system specification>, refs) **then**

```

let packages =
  { p ∈ ( refs.toSet ∩ <package definition> ) : p.surroundingScopeUnit0 = undefined } in
    mk-Sdl-specification(Mapping(s), { Mapping(p): p ∈ packages },)

There shall be a  $\langle \text{qualifier} \rangle$  in  $\langle \text{package} \rangle\text{-}\langle \text{identifier} \rangle$  only if the package is logically contained in another package.

$$\forall ds1, ds2 \in \langle \text{definition selection} \rangle:$$
$$(ds1.parentAS0 = ds2.parentAS0 \wedge ds1 \neq ds2) \Rightarrow$$
$$(ds1.s\text{-}\langle \text{selected entity kind} \rangle \neq ds2.s\text{-}\langle \text{selected entity kind} \rangle \vee ds1.s\text{-}\langle \text{name} \rangle \neq ds2.s\text{-}\langle \text{name} \rangle)$$

Any pair of ( $\langle \text{selected entity kind} \rangle$ ,  $\langle \text{name} \rangle$ ) shall be distinct within a  $\langle \text{definition selection list} \rangle$ .

$$\forall ds \in \langle \text{definition selection} \rangle: ds.parentAS0 \in \langle \text{package public} \rangle \Rightarrow$$
$$(\exists! d \in ENTITYDEFINITION0 \cup REFERENCE0 :$$
$$d.surroundingScopeUnit0 = ds.surroundingScopeUnit0 \wedge d.entityName0 = ds.s\text{-}\langle \text{name} \rangle \wedge$$
$$\mathbf{if} \ ds.s\text{-}\langle \text{selected entity kind} \rangle = \text{undefined}$$
$$\mathbf{then} \ \text{true}$$
$$\mathbf{else} \ d.entityKind0 = ds.s\text{-}\langle \text{selected entity kind} \rangle$$
$$\mathbf{endif})$$

For a  $\langle \text{definition selection} \rangle$  in a  $\langle \text{package public} \rangle$  clause, the  $\langle \text{selected entity kind} \rangle$  is allowed to be omitted only if the name is used for just one defining occurrence directly in the  $\langle \text{package} \rangle$ . For a  $\langle \text{definition selection} \rangle$  in  $\langle \text{package public} \rangle$ , if the  $\langle \text{selected entity kind} \rangle$  is not omitted there shall exist an entity definition having the same entity kind and the same name in the package.

$$\forall uc \in \langle \text{package use clause} \rangle: \forall ds \in \langle \text{definition selection} \rangle:$$
$$\mathbf{let} \ pd = uc.usedPackage0 \ \mathbf{in}$$
$$ds.parentAS0 = uc \wedge ds.s\text{-}\langle \text{selected entity kind} \rangle = \text{undefined} \Rightarrow$$
$$((\exists! ds1 \in \langle \text{definition selection} \rangle:$$
$$ds1.surroundingScopeUnit0 = pd \wedge ds1.s\text{-}\langle \text{name} \rangle = ds1.s\text{-}\langle \text{name} \rangle) \vee$$
$$((pd.s\text{-}\langle \text{package heading} \rangle.s\text{-}\langle \text{package public} \rangle = \text{undefined}) \wedge$$
$$(\exists! d \in ENTITYDEFINITION0 \cup REFERENCE0 :$$
$$d.surroundingScopeUnit0 = pd \wedge d.entityName0 = ds.s\text{-}\langle \text{name} \rangle)))$$
$$\mathbf{endlet}$$

For a  $\langle \text{definition selection} \rangle$  in a  $\langle \text{package use clause} \rangle$ ,  $\langle \text{selected entity kind} \rangle$  is allowed to be omitted if and only if either exactly one entity of that name is mentioned in any  $\langle \text{definition selection list} \rangle$  for the package or the package has no  $\langle \text{definition selection list} \rangle$  and directly contains a unique definition of that name.

## Transformations

$$\mathbf{let} \ usePredef = \langle \text{package use clause} \rangle(\$$
$$\langle \text{identifier} \rangle(\text{empty}, \langle \text{name} \rangle(\text{"Predefined"})), \text{undefined}) \ \mathbf{in}$$
$$\langle \text{package definition} \rangle(\text{uses}, \text{heading}, \text{entities})$$
$$\mathbf{provided} \ \text{uses.head} \neq usePredef$$
$$=6=> \ \mathbf{mk}\text{-}\langle \text{package definition} \rangle(\langle usePredef \rangle \hat{\ } \text{uses}, \text{heading}, \text{entities})$$
$$\mathbf{endlet}$$
$$\mathbf{let} \ usePredef = \langle \text{package use clause} \rangle(\$$
$$\langle \text{identifier} \rangle(\text{empty}, \langle \text{name} \rangle(\text{"Predefined"})), \text{undefined}) \ \mathbf{in}$$
$$\langle \text{system definition} \rangle(\text{uses}, \text{heading}, \text{struct})$$
$$\mathbf{provided} \ \text{uses.head} \neq usePredef$$
$$=6=> \ \mathbf{mk}\text{-}\langle \text{system definition} \rangle(\langle usePredef \rangle \hat{\ } \text{uses}, \text{heading}, \text{struct})$$

**endlet**

The *Package-definition-set* of an *Sdl-specification* always includes the *Package-definition* of **package** `Predefined` defined in [ITU-T Z.104]; consequently this package does not have to be explicitly included as a <referenced definition>. See clause 7.1 *Model* of [ITU-T Z.101].

```
<<package use clause>(id, sel1) > ^ something ^ <<package use clause>(id, sel2) >
=6=>
  (let newSel =
    if sel1 = undefined then empty
    elseif sel2 = undefined then empty
    else sel1 ^ <s in sel2: (s ∉ sel1.toSet) >
    endif
  in
    <mk-<package use clause>(id, newSel) > ^ something
  endlet)
```

If a package is mentioned in several <package use clause> items of a definition (in the same text area or different text areas of the definition), these are replaced by one <package use clause> that selects the union of the definitions selected in the <package use clause> items. See clause 7.2 *Model* of [ITU-T Z.101].

### Mapping to abstract syntax

```
| <package definition>(*, <package heading>(*, n, *), entities) then
let entitiesSet = { Mapping(entities[i]:i ∈ 1..entities.length) in
mk-Package-definition(n,
  { pkd ∈ entitiesSet: (pkd ∈ Package-definition) },
  { dtd ∈ entitiesSet: (dtd ∈ Data-type-definition) }
  ∪ { implicitInterface1(afd) | (afd ∈ entitiesSet ∧ afd ∈ Agent-type-definition) }
  ∪ { choiceForInterface1(if) : (if in entities ∧ if ∈ <interface definition> ) } // choices for Interface-defs
  ∪ { typeForSignal1(sd) ∈ Data-type-definition:
    (sd ∈ <signal definition> ∧ sd.parentASO ∈ <signal definition list> ∧ sd.parentASO in entities)},
  { snd ∈ entitiesSet: (snd ∈ Syntype-definition) }
  ∪ { typeForSignal1(sd) ∈ Syntype-definition:
    (sd ∈ <signal definition> ∧ sd.parentASO ∈ <signal definition list> ∧ sd.parentASO in entities)},
  { sgd ∈ entitiesSet: (sgd ∈ Signal-definition) },
  { atd ∈ entitiesSet: (atd ∈ Agent-type-definition) },
  { std ∈ entitiesSet: (std ∈ Composite-state-type-definition) },
  { pdf ∈ entitiesSet: (pdf ∈ Procedure-definition) } )
endlet // entitiesSet
```

### Auxiliary functions

The function *usedPackageDefinitionList0* gets the used package definition list of a scope unit.

```
usedPackageDefinitionList0(su: SCOPEUNIT0): <package definition>* =def
  < u.usedPackage0 | u in su.s-<package use clause>-seq >
```

The function *usedPackage0* gets the package definition for a <package use clause>.

```
usedPackage0(uc: <package use clause>): <package definition> =def
  getEntityDefinition0(uc.s-<identifier>, package)
```

The function *implicitInterface1* returns the implicit interface definition associated with an *Agent-type-definition* or an *Agent-definition* or a *State-machine*. See clause F2.2.9.2.

```
implicitInterface1(d: Agent-definition ∪ Agent-type-definition ∪ State-machine): Interface-definition =def
case d of
| Agent-definition then
let sigDefs = getEntityDefinition1(d.s-Agent-type-identifier, agent type).s-Signal-definition-set in
mk-Interface-definition(d.s-Agent-name, // Sort name – same as the agent
```

```

    mk-Literal-signature(mk-Name("null"),
      mk-Result(mk-Identifier(Mapping(d.fullQualifier0), d.s-Agent-type-name),
        mk-Result-aggregation(REF)),
      0),
    empty, // Data-type-identifier-set
    sigDefs, // Signal-definition-set
    d.baseType1.inputSignalSet1 ∪ { sd.identifier1 | sd ∈ sigDefs } // Signal-identifier-set
  )
endlet
| Agent-type-definition then
let sigDefs = d.s-Signal-definition-set in
  mk-Interface-definition (d.s-Agent-type-name,
    mk-Literal-signature(mk-Name("null"),
      mk-Result(mk-Identifier(Mapping(d.fullQualifier0), d.s-Agent-type-name),
        mk-Result-aggregation(REF)),
      0),
    empty,
    sigDefs, // Signal-definition-set
    d.baseType1.inputSignalSet1 ∪ { sd.identifier1 | sd ∈ sigDefs } // Signal-identifier-set
  )
endlet
| State-machine then
  mk-Interface-definition (d.s-State-name,
    mk-Literal-signature(mk-Name("null"),
      mk-Result(mk-Identifier(Mapping(d.fullQualifier0), d.s-State-name),
        mk-Result-aggregation(REF)),
      0),
    empty,
    ∅ // empty Signal-definition-set
    let parent =
      parentAS1ofKind(d, Agent-definition ∪ Agent-type-definition) in
    let siblings =
      if parent ∈ Agent-definition
      then parent.s-Agent-type-definition.s-Agent-definition-set
      else parent.s-Agent-definition-set
      endif in
    (parent.implicitInterface1.s-Signal-identifier-set // parent interface signals
      \ { siblingsig ∈ sibling.implicitInterface1 : sibling ∈ siblings } ) // except to siblings
    ∪ d.baseType1.inputSignalSet1 // incoming signals of composite state type of state machine
    endlet // siblings
    endlet // parent
  )
endcase

```

The implicit *Interface-definition* for an agent type (or agent or state machine) has a *Sort* with the same *Name* as the agent type (or agent or state machine respectively). See clause 12.1.2 *Semantics* of [ITU-T Z.101].

The implicit *Interface-definition* defined by a state machine of an agent type contains (in its interface specialization – see [ITU-T Z.104]) the interface defined by the agent type itself except any part of that interface concerned only with contained agents. The interface also contains in its interface specialization all interfaces given in the incoming signal lists associated with any gates of the state machine. The interface also contains in its <interface use list> all signals given in the incoming signal lists associated with gates of the state machine. See clause 12.1.2 *Semantics* of [ITU-T Z.101].

### F2.2.4.3 Referenced definition

#### Concrete syntax

```

<referenced definition> =
  <definition>
<definition> =

```

| <package definition>  
 | <agent definition>  
 | <agent type definition>  
 | <composite state definition>  
 | <composite state type definition>  
 | <procedure definition>  
 | <operation definition>

<package reference> :: <package><identifier>  
 <procedure reference> :: <procedure reference heading>  
 <procedure reference heading> ::  
   <type preamble> [ <exported> ] [ <qualifier> ] <procedure><name> [ <formal context parameters> ]  
 <block reference> :: <block><name> <number of instances>  
 <process reference> :: <process><name> <number of instances>  
 <composite state reference> :: <composite state name>  
 <agent type reference> =  
   <system type reference>  
   | <block type reference>  
   | <process type reference>  
 <system type reference> :: <system type><identifier> [ <formal context parameters> ]  
 <block type reference> :: <type preamble> <block type><identifier> [ <formal context parameters> ]  
 <process type reference> :: <type preamble> <process type><identifier> [ <formal context parameters> ]  
 <composite state type reference> :: <type preamble> <composite state type><identifier>

### Conditions on concrete syntax

Except as mentioned below (for <formal context parameters>) the following conditions are derived from clause 7.3 of [ITU-T Z.101].

$$\forall refDef \in \langle \text{referenced definition} \rangle : refDef.referecndedBy0 \neq \text{undefined} \wedge refDef.parentAS0 = \langle \text{sdl specification} \rangle$$

$$\vee (refDef \in \langle \text{package definition} \rangle \wedge refDef.contextQualifier0 = \text{undefined})$$

For each <referenced definition> except any outermost <package definition>, there shall be a reference in the associated <package> or <system specification>.

$$\forall ref \in REFERENCE0 : ref.referecndDefinition0 \neq \text{undefined}$$

For each reference, there shall exist a <referenced definition> with the same entity kind as the reference, and whose <qualifier>, if present, denotes a path, from a scope unit enclosing the reference, to the reference.

$$\forall ref \in REFERENCE0 : \forall refDef \in \langle \text{referenced definition} \rangle :$$

$$ref.s-\langle \text{formal context parameters} \rangle \neq \text{undefined} \wedge refDef = ref.referecndDefinition0 \Rightarrow$$

$$refDef.s-\langle \text{formal context parameters} \rangle \neq \text{undefined} \wedge$$

$$isFormalContextParametersMatched0(ref, refDef)$$

If there is a <formal context parameters> item in the type reference, this shall be the same as the <formal context parameters> of the <referenced definition>. See clause 8.2 of [ITU-T Z.103].

$$\forall ref \in \langle \text{block reference} \rangle \cup \langle \text{process reference} \rangle : \forall refDef \in \langle \text{referenced definition} \rangle :$$

**let**  $refDefInstances =$

**if**  $refDef \in \langle \text{block definition} \rangle$

**then**  $refDef.s-\langle \text{block heading} \rangle.s-\langle \text{agent instantiation} \rangle.s-\langle \text{number of instances} \rangle$

**else**  $refDef.s-\langle \text{process heading} \rangle.s-\langle \text{agent instantiation} \rangle.s-\langle \text{number of instances} \rangle$

**endif**

**in**

$$refDef = ref.referecndDefinition0 \wedge refDefInstances \neq \text{undefined} \wedge ref.s-\langle \text{number of instances} \rangle \neq \text{undefined}$$

$$\Rightarrow$$

$$refDefInstances = ref.s-\langle \text{number of instances} \rangle$$

**endlet** //  $refDefInstances$

If both the <number of instances> in the <agent instantiation> of an <agent definition> and the <number of instances> in the agent reference for the <agent definition> are specified, the two <number of instances> shall be equal. See clause 9 *Concrete grammar* of [ITU-T Z.103].

$$\begin{aligned} &\forall \text{ref1}, \text{ref2} \in \langle \text{referenced definition} \rangle: \\ &\quad \text{ref1.entityName0} = \text{ref2.entityName0} \wedge \text{ref1.entityKind0} = \text{ref2.entityKind0} \wedge \text{ref1} \neq \text{ref2} \Rightarrow \\ &\quad \text{ref1.contextQualifier0} \neq \text{undefined} \wedge \text{ref2.contextQualifier0} \neq \text{undefined} \wedge \\ &\quad \neg \text{isPathItemMatched0}(\text{ref1.contextQualifier0.s-}\langle \text{path item} \rangle\text{-seq}, \\ &\quad \text{ref2.contextQualifier0.s-}\langle \text{path item} \rangle\text{-seq}) \wedge \\ &\quad \neg \text{isPathItemMatched0}(\text{ref2.contextQualifier0.s-}\langle \text{path item} \rangle\text{-seq}, \\ &\quad \text{ref1.contextQualifier0.s-}\langle \text{path item} \rangle\text{-seq}) \end{aligned}$$

If two <referenced definition> items of the same entity kind have the same <name>, the <qualifier> of one shall not constitute the leftmost part of the other <qualifier>, and neither <qualifier> is allowed to be omitted. See clause 7.3 *Concrete grammar* of [ITU-T Z.103].

$$\begin{aligned} &\forall \text{rd} \in \langle \text{referenced definition} \rangle: \\ &\quad ( \text{rd} \in \langle \text{package definition} \rangle \\ &\quad \wedge (\exists \text{ref} \in \langle \text{package reference} \rangle : \text{ref.s-}\langle \text{identifier} \rangle.\text{refersto0} = \text{rd}) ) \\ &\quad \Rightarrow \text{rd.contextQualifier0} \neq \text{undefined} \end{aligned}$$

The <qualifier> in a <referenced definition> shall be present if the <referenced definition> is a <package definition> referenced from another context except if the <package definition> represents an outermost package definition.

$$\forall \text{def} \in \text{ENTITYDEFINITION0}: \text{def} \notin \langle \text{referenced definition} \rangle \Rightarrow \text{def.contextQualifier0} = \text{undefined}$$

It is not allowed to specify a <qualifier> after the initial keyword(s) for definitions which are not <referenced definition> items.

## Transformations

$$\begin{aligned} \text{pk} &= \langle \text{package reference} \rangle(*) = 4 \Rightarrow \text{adaptDefinition}(\text{pk.referencedDefinition0}, \text{undefined}) \\ \text{pr} &= \langle \text{procedure reference} \rangle(*, *) = 4 \Rightarrow \text{adaptDefinition}(\text{pr.referencedDefinition0}, \text{undefined}) \\ \text{bk} &= \langle \text{block reference} \rangle(*, \text{inst}) = 4 \Rightarrow \text{adaptDefinition}(\text{bk.referencedDefinition0}, \text{inst}) \\ \text{ps} &= \langle \text{process reference} \rangle(*, \text{inst}) = 4 \Rightarrow \text{adaptDefinition}(\text{ps.referencedDefinition0}, \text{inst}) \\ \text{cs} &= \langle \text{composite state reference} \rangle(*) = 4 \Rightarrow \text{adaptDefinition}(\text{cs.referencedDefinition0}, \text{undefined}) \\ \text{st} &= \langle \text{system type reference} \rangle(*) = 4 \Rightarrow \text{adaptDefinition}(\text{st.referencedDefinition0}, \text{undefined}) \\ \text{bt} &= \langle \text{block type reference} \rangle(*, *) = 4 \Rightarrow \text{adaptDefinition}(\text{bt.referencedDefinition0}, \text{undefined}) \\ \text{pt} &= \langle \text{process type reference} \rangle(*, *) = 4 \Rightarrow \text{adaptDefinition}(\text{pt.referencedDefinition0}, \text{undefined}) \\ \text{ct} &= \langle \text{composite state type reference} \rangle(*, *) = 4 \Rightarrow \text{adaptDefinition}(\text{ct.referencedDefinition0}, \text{undefined}) \\ \text{op} &= \langle \text{operation reference} \rangle(*, *) = 4 \Rightarrow \text{adaptDefinition}(\text{op.referencedDefinition0}, \text{undefined}) \end{aligned}$$

The referenced definition is logically placed at the point of the reference to determine the properties of the system specification (see clause 7.3 of [ITU-T Z.101]).

## Auxiliary functions

The function *referencedDefinition0* finds the corresponding entity definition for a given reference.

```
referencedDefinition0(ref: REFERENCE0): <referenced definition> =def
  let eKind = ref.referenceKind0 in
  let refName = ref.referenceName0 in
  if (∃! d ∈ <referenced definition>:
```

```

    isAncestorAS0(d.parentAS0, ref) ∧ d.entityName0 = refName ∧ d.entityKind0 = eKind)
then
let d = take({d∈<referenced definition>:
    isAncestorAS0(d.parentAS0, ref) ∧ d.entityName0 = refName ∧ d.entityKind0 = eKind})
in
    if isQualifierMatched0(d.contextQualifier0, ref.surroundingScopeUnit0)
    then d
    else undefined
    endif
endlet // d
else
    undefined
endif
endlet // refName
endlet // eKind

```

The function *referencedBy0* finds the corresponding reference for a <referenced definition>.

```

referencedBy0(rd: <referenced definition>): REFERENCE0 =def
    take({ ref∈ REFERENCE0 : ref.referencedDefinition0 = rd})

```

The function *isPathItemMatched0* is used to determine if the first path item constitutes the leftmost part of the second path item.

```

isPathItemMatched0(seq1: <path item>*, seq2: <path item>*): BOOLEAN =def
    (seq1.length ≤ seq2.length ∧
    (∀ i ∈ 1..seq1.length:
        seq1[i].s-<name> = seq2[i].s-<name> ∧
        seq1[i].s-<scope unit kind> = seq2[i].s-<scope unit kind> ) )

```

The function *adaptDefinition* is used to adapt an inserted referenced definition: the qualifier is defined by context therefore is *undefined* in the syntax, and the number of instances is merged.

```

adaptDefinition(def:<referenced definition>, inst:<number of instances>):<referenced definition> =def
case def of
| <package definition>(uses, <package heading>(*, name, intf), entities)
then mk-<package definition>(uses, mk-<package heading>(undefined, name, intf), entities)
| <internal procedure definition>(uses,
    <procedure heading>(h1, *, name, h2, h3, h4, h5, h6, h7),
    entities, body)
then mk-<internal procedure definition>(uses,
    mk-<procedure heading>(h1, undefined, name, h2, h3, h4, h5, h6, h7),
    entities, body)
| <block definition>(uses, <block heading>(*, name, <agent instantiation>(inst1, addi)), body)
then mk-<block definition>(uses, mk-<block heading>(undefined, name,
    mk-<agent instantiation>(mergeNumbers(inst, inst1), addi)), body)
| <process definition>(uses,
    <process heading>(*, name, <agent instantiation>(inst1, addi)), body)
then mk-<process definition>(uses, mk-<process heading>(undefined, name,
    mk-<agent instantiation>(mergeNumbers(inst, inst1), addi)), body)
| <interface definition> then def
| <composite state definition>(uses, <composite state heading>(*, name, p), body)
then mk-<composite state definition>(uses, mk-<composite state heading>(undefined, name, p), body)
| <system type definition>(uses, <system type heading>(*, name, addi), body)
then mk-<system type definition>(uses, mk-<system type heading>(undefined, name, addi), body)
| <block type definition>(uses, <block type heading>(pre, *, name, addi), body)
then mk-<block type definition>(uses, mk-<block type heading>(pre, undefined, name, addi), body)
| <process type definition>(uses, <process type heading>(pre, *, name, addi), body)
then mk-<process type definition>(uses, mk-<process type heading>(pre, undefined, name, addi), body)
| <composite state type definition>(compkind)
then
    case compkind of
    | <composite state type graph>(uses, <composite state type heading>(virt, *, name, fp, vc, sp, afp), css, *)

```

```

then mk-<composite state type definition>(uses,
  mk-<composite state type heading>(virt, undefined, name, fp, vc, sp, AFP),
  CSS,
  name) // composite state type graph
endcase
| <state aggregation type>(uses,<state aggregation type heading>(pre, *, name, fp, vc, sp, AFP), as,*)
  then mk-<state aggregation type>(uses,
    mk-<state aggregation type heading>(pre, undefined, name, fp, vc, sp, AFP),
    as,
    name) // state aggregation type
| <operation definition>(uses, <operation heading>(opkind, pre, *, name, pars, res), entities, body)
  then mk-<operation definition>(uses,
    mk-<operation heading>(opkind, pre, undefined, name, pars, res),
    entities,
    body)
otherwise undefined
endcase

```

The function *mergeNumbers* is used to adapt an inserted referenced definition.

```

mergeNumbers(inst1: <number of instances>, inst2: <number of instances>):
<number of instances> =def
  if inst1 = undefined then inst2
  elseif inst2 = undefined then inst1
  else
    let ini1 = inst1.s-<initial number> in
    let max1 = inst1.s-<maximum number> in
    let lower1 = inst1.s-<lower bound> in
      mk-<number of instances>(if ini1 ≠ undefined then ini1 else inst2.s-<initial number> endif,
        if max1 ≠ undefined then max1 else inst2.s-<maximum number> endif,
        if lower1 ≠ undefined then lower1 else inst2.s-<lower bound> endif
      ) // number of instances
    endlet // lower1
    endlet // max1
    endlet // ini1
  endif // both inst1 and inst2 defined

```

The function *isFormalContextParametersMatched0* is used to determine if two <formal context parameters> match.

```

isFormalContextParametersMatched0(fcp1: <name>*, fcp2: <name>*): BOOLEAN =def
  if (fcp1 = empty) then (fcp2 = empty)
  else
    isFormalContextParameterMatched0(fcp1.head, fcp1.tail) ∧
    isFormalContextParametersMatched0 (fcp1.tail, fcp2.tail)
  endif

```

```

isFormalContextParameterMatched0(fcp1: <name>*, fcp2: <name>*): BOOLEAN =def
  if (fcp1 ∈ <agent type context parameter>) then (fcp2 ∈ <agent type context parameter>)
  elseif (fcp1 ∈ <agent context parameter>) then (fcp2 ∈ <agent context parameter>)
  elseif (fcp1 ∈ <procedure context parameter>) then (fcp2 ∈ <procedure context parameter>)
  elseif (fcp1 ∈ <remote procedure context parameter>) then (fcp2 ∈ <remote procedure context parameter>)
  elseif (fcp1 ∈ <signal context parameter>) then (fcp2 ∈ <signal context parameter>)
  elseif (fcp1 ∈ <variable context parameter>) then (fcp2 ∈ <variable context parameter>)
  elseif (fcp1 ∈ <remotevariable context parameter>) then (fcp2 ∈ <remotevariable context parameter>)
  elseif (fcp1 ∈ <timer context parameter list>) then (fcp2 ∈ <timer context parameter list>)
  elseif (fcp1 ∈ <synonym context parameter list>) then (fcp2 ∈ <synonym context parameter list>)
  elseif (fcp1 ∈ <sort context parameter>) then (fcp2 ∈ <sort context parameter>)
  elseif (fcp1 ∈ <compositestate type context parameter>)
    then (fcp2 ∈ <compositestate type context parameter>)
  elseif (fcp1 ∈ <gate context parameter>) then (fcp2 ∈ <gate context parameter>)
  elseif (fcp1 ∈ <interface context parameter list>) then (fcp2 ∈ <interface context parameter list>)

```

endif

#### F2.2.4.4 Select definition

##### Concrete syntax

```
<select definition> ::  
  <Boolean><simple expression>  
  {  
    <agent definition>  
    | <agent type definition>  
    | <agent type reference>  
    | <block reference>  
    | <channel definition>  
    | <channel to channel connection>  
    | <composite state reference>  
    | <composite state type definition>  
    | <composite state type reference>  
    | <composite state definition>  
    | <data definition>  
    | <imported procedure specification>  
    | <imported variable specification>  
    | <macro definition>  
    | <operation definition>  
    | <package definition>  
    | <package reference>  
    | <procedure definition>  
    | <procedure reference>  
    | <process reference>  
    | <remote procedure definition>  
    | <remote variable definition>  
    | <select definition>  
    | <signal definition list>  
    | <signal list definition>  
    | <state machine>  
    | <state partition>  
    | <timer definition>  
    | <variable definition> }+
```

##### Transformations

```
<select definition>(cond, defs)  
=7=> if value0(cond) = 0 then defs else empty endif
```

If the result of the `<Boolean><simple expression>` of a `<select definition>` is the predefined Boolean value false, the constructs contained in the `<select definition>` are not selected. In the other case, the constructs are selected. The `<select definition>` is deleted at transformation and is replaced by the contained selected constructs, if any. See clause 13.1 *Model* of [ITU-T Z.102].

##### Auxiliary functions

The function `value0` computes the Natural value for a simple expression from the *Literal-signature* returned by `value1`. The Boolean values do not have any defined *Literal-natural* values, so true is treated as 0 and false is treated as 1.

```
value0(e:<simple expression>): NAT =def  
  if isSuperType1(getEntityDefinition1(predefinedId1("Boolean"), sort).s-Sort,  
    value1(e.simpleMapping).s-Result.s-Sort-reference-identifier)  
  then  
    if value1(e.simpleMapping).s-Literal-name = mk-Name("true") then 0 else 1 endif  
  else  
    value1(e.simpleMapping).s-Literal-natural  
  endif
```

The function *simpleMapping* generates a *Constant-expression* for a <simple expression>. It assumes that transformations of infix operators into operator applications have taken place, and makes use of the restriction that only predefined literals and operations can be used in the <simple expression>.

```

simpleMapping(e:<simple expression>): Constant-expression =def
  case e of
  | <operand5>(undefined, <operator application>(ident, params)) then
    mk-Operation-application(Mapping(ident), <simpleMapping>(x) | x in params)
  | <operand5>(undefined, <literal identifier>(qual, name)) then
    mk-Identifier(Mapping (qual), Mapping (name))
  | <operand5>(undefined, <conditional expression>(e1, e2, e3)) then
    mk-Conditional-expression(simpleMapping (e1), simpleMapping (e2), simpleMapping (e3))
  otherwise undefined
endcase

```

## F2.2.4.5 Transition option

### Concrete syntax

```

<transition option> :: <alternative question> <textual decision body>
<alternative question> = <simple expression> | <informal text>

```

### Transformations

```

t=<transition action items>(a, undefined)
provided a.last ∉ <transition option> ∧ t.parentAS0.parentAS0.parentAS0 ∈ <transition option> ∧
t.findContinueLabel ≠ undefined
=7=> mk-<transition action items>(a,
  mk-<terminator>(undefined, mk-<join>( t.findContinueLabel)))

```

If a <transition option> is not terminating, then it is derived syntax for a <transition option> wherein all the <textual answer part>s and the <textual else part> have inserted in their <transition>:

- if the transition option is the last <action> in a <transition string>, a <join> to the following <terminator>; or
- else a <join> to the first <action> following the transition option.

```

<transition option>(q, <textual decision body>(answers, elsePart))
=7=> (let matching = { a.s-<transition> | a ∈ answers.toSet: q.value0 ∈ a.s-<answer> } in
  if matching ≠ ∅ then matching.take
  elseif elsePart ≠ undefined then elsePart.s-<transition>
  else undefined
endif
endlet)

```

The <transition> of a <textual answer part> is selected if the <answer> contains the result of the <alternative question>. If no <answer> contains the result of the <alternative question>, the <transition> of the <else part> is selected.

If no <else part> is provided and none of the outgoing paths are selected, the selection is invalid.

On transformation each <transition> not selected is deleted, and the <transition option> is deleted and replaced by the selected <transition>.

## F2.2.5 Structural concepts

### F2.2.5.1 Structural type definitions

#### F2.2.5.1.1 Agent types

#### Abstract syntax

```

Agent-type-definition      ::      Agent-type-name

```

*Agent-kind*  
 [ *Agent-type-identifier* ]  
*Agent-formal-parameter\**  
*Data-type-definition-set*  
*Syntax-definition-set*  
*Signal-definition-set*  
*Timer-definition-set*  
*Variable-definition-set*  
*Agent-type-definition-set*  
*Composite-state-type-definition-set*  
*Procedure-definition-set*  
*Agent-definition-set*  
*Gate-definition-set*  
*Channel-definition-set*  
*State-machine*  
 [ *Abstract* ]

*Agent-kind* = **SYSTEM** | **BLOCK** | **PROCESS**

### Conditions on abstract syntax

$\forall std \in \text{Agent-type-definition}: std.agentKindI = \mathbf{SYSTEM} \Rightarrow$   
 $\neg ((\exists atd \in \text{Agent-type-definition}) : (isAncestorASI(atd, std)))$

A system type definition (an *Agent-type-definition* with *Agent-kind* **SYSTEM**) shall not be logically contained in any other *Agent-type-definition*. See clause 8.1.1.1 *Abstract grammar* of [ITU-T Z.101].

$\forall d \in \text{Agent-type-definition}: (d.agentKindI = \mathbf{PROCESS}) \Rightarrow$   
 $(\forall d1 \in \text{Agent-type-definition} \cup \text{Agent-definition}: d1.parentASI = d \Rightarrow d1.agentKindI = \mathbf{PROCESS})$

A process type definition (an *Agent-type-definition* with *Agent-kind* **PROCESS**) shall not contain a block type definition (an *Agent-type-definition* with *Agent-kind* **BLOCK**) or a block definition (an *Agent-definition* with *Agent-kind* **BLOCK**). See clause 8.1.1.1 *Abstract grammar* of [ITU-T Z.101].

### Concrete syntax

<agent type definition> =  
     <system type definition>

```

```

        <type expression>(cst.identifier0, empty)
    ) ) )
endlet // cst
endlet // afps
endlet // atd
endlet // tbcsn

```

The following paragraphs are derived from clause 8.1.1.1 *Model* of [ITU-T Z.103].

If an <agent type definition> (a <system type definition>, <block type definition> or <process type definition>) has an <agent structure> that contains an <agent body> instead of an <interaction>, this is shorthand for an agent type that has no contained agents and a state machine with its type defined by the <agent body>.

A <composite state type definition> is derived from the <agent type definition>. This definition is given a heading with the same <virtuality>, an anonymous name, the same <formal context parameters> and same <agent formal parameters> as the <agent type definition>. The <agent body> is copied as the <composite state body> and any part of a <qualifier> in the body that refers to the enclosing agent type is changed to refer to the composite state type of the agent type. Each <textual gate definition> of the <agent type definition> is copied as a <textual gate definition> of the <composite state type definition> but omitting any <textual endpoint constraint> of the <gate constraint>. Each <textual interface gate definition> of the <agent type definition> is copied as a <textual interface gate definition> of the <composite state type definition> but omitting any <textual endpoint constraint>. A <composite state type reference> for the derived <composite state type definition> is placed in the <agent type definition>. In the <agent type definition>, the <agent body> is replaced by a <state machine> with a <typebased composite state> that has:

- an anonymous unique name as the <composite state name>;
- the list of names for the <agent formal parameters> of the agent type as the <actual parameters> in the <nextstate parameters> and with no **via** <state entry point> in the <nextstate parameters>;
- the (anonymous) name of the composite state type as the <base type> in the <composite state type expression> and the list of names of the <formal context parameters> (if any) of the agent type as the <actual context parameters> in the <composite state type expression>.

Each <channel definition> of the <agent type definition> that had a <channel path> with one <channel endpoint> connected to a <gate> of the environment (**env**) and the other <channel endpoint> connected to the <agent body>, has the <channel endpoint> that was connected to the <agent body> changed to connect to the <gate> with the same name (as the gate of the environment) of the replacement <state machine>. If the <channel definition> has two <channel path> items, the change is made to both <channel path> items.

NOTE – [ITU-T Z.103] describes (see text above) the insertion of a composite state type reference for the derived composite state type in the agent type, but such references are removed and replaced by the referenced definition (in this case the <composite state type definition> which is in the <interaction> that replaces the <agent body> of the <agent structure>).

If the <agent type definition> is defined as a specialization by inheriting another agent type (the supertype), the composite state type of the state machine of the supertype has to be **virtual** and the composite state type name is the same in both the supertype and subtype, because the copied <agent body> adds to the supertype. See clause 8.1.1.1 *Model* of [ITU-T Z.103].

### Auxiliary functions

The function *deriveGateEntities0* derives the gates from the entities of an <agent structure> to insert as entities of the <composite state type definition> according to the clause 8.1.1.1 *Model* of [ITU-T Z.103].

```

deriveGateEntities0(entities: <entity in agent>*):<entity in composite state>* =def

```

```

deriveGateEntity0(entities.head) ^
  (if entities.length = 1 then empty else deriveGateEntities0(entities.tail) endif)

```

The function *deriveGateEntity0* given an <entity in agent>, if it is a gate returns a one element <entity in composite state> list to insert as an entity of <composite state type definition> according to the clause 8.1.1.1 *Model* of [ITU-T Z.103]. For any other <entity in agent> an empty list is returned.

```

deriveGateEntity0(entity: <entity in agent>):<entity in composite state>* =def
case entity of
| <textual gate definition>( g, enc, <gate constraint>( in,*, sin, out,*, sout ) ) then
  < mk-<textual gate definition>( g, enc, mk-<gate constraint>( in, undefined, sin, out, undefined, sout ) ) >
| <textual gate definition>( g, enc, <gate constraint>( inout, *, , sinout) ) then
  < mk-<textual gate definition>( g, enc, mk-<gate constraint>( inout, undefined, sinout ) ) >
| <textual interface gate definition>( inout, interface, encoding, * ) then
  < mk-<textual interface gate definition>( inout, interface, encoding, undefined ) >
otherwise empty
endcase

```

The function *deriveChannelEntities0* derives the channels from the entities of an <agent structure> to insert as entities of an <interaction> that replaces an <agent body> of the <agent structure> according to the clause 8.1.1.1 *Model* of [ITU-T Z.103]. The <name> parameter is the name of the type based composite state.

```

deriveChannelEntities0(entities: <entity in agent>*, tbcns: <name>):<entity in composite state>* =def
  deriveChannelEntity0(entities.head, tbcns) ^
  (if entities.length = 1 then empty else deriveChannelEntities0(entities.tail, tbcns) endif)

```

The function *deriveChannelEntity0* given an <entity in agent> if it is a gate returns a one element <entity in composite state> list to insert in the <interaction> that replaces an <agent body> of the <agent structure> according to the clause 8.1.1.1 *Model* of [ITU-T Z.103]. For any other <entity in agent> an empty list is returned. The <name> parameter is the name of the type based composite state.

```

deriveChannelEntity0(entity: <entity in agent>, tbcns: <name>):<entity in composite state>* =def
case entity of
| <channel definition>( n, e, d,
  <channel path>( <channel endpoint>( e1, g1 ), <channel endpoint>( e2, g2 ), sl ), undefined )
then
  if e1 = env
  then
    < mk-<channel definition>( n, e, d,
      mk-<channel path>( mk-<channel endpoint> env, g1 ), mk-<channel endpoint>( tbcns, g1 ), sl ),
      undefined ) >
  elseif e2 = env
    < mk-<channel definition>( n, e, d,
      mk-<channel path>( mk-<channel endpoint>( tbcns, g2 ), mk-<channel endpoint>( env, g2 ), sl ),
      undefined ) >
  else empty
  endif
| <channel definition>( n, e, d,
  <channel path>( <channel endpoint>( e1, g1 ), <channel endpoint>( e2, g2 ), sl1 ),
  <channel path>( <channel endpoint>( e2, g2 ), <channel endpoint>( e1, g1 ), sl2 ) )
then
  if e1 = env
  then
    < mk-<channel definition>( n, e, d,
      mk-<channel path>( mk-<channel endpoint>( env, g1 ), mk-<channel endpoint>( tbcns, g1 ), sl1 ),
      mk-<channel path>( mk-<channel endpoint>( tbcns, g1 ), mk-<channel endpoint>( env, g1 ), sl2 ) ) >
  elseif e2 = env
    < mk-<channel definition>( n, e, d,
      mk-<channel path>( mk-<channel endpoint>( tbcns, g2 ), mk-<channel endpoint>( env, g2 ), sl1 ),
      mk-<channel path>( mk-<channel endpoint>( tbcns, g2 ), mk-<channel endpoint>( env, g2 ), sl1 ),
      undefined ) >

```

```

    mk-<channel path>(mk-<channel endpoint>(env,g2),mk-<channel endpoint>(tbcsn,g2), s12) >
  else empty
endif
otherwise empty
endcase

```

The function *actualParamsNextstate0* derives the <actual parameters> in the <nextstate parameters> from <agent formal parameters> for a type based composite state in the transform of <agent structure>. The <agent formal parameters> has to be expanded so that each <parameters of sort> contains only one <name>.

```

actualParamsNextstate0(afps: <agent formal parameters>):<actual parameters> =def
  if afps = empty then empty
  else
    < mk-<operand5>(mk-<variable access>(
      mk-<identifier>(empty, afps.head.s-<parameters of sort>.s-<name>-seq[1]))
    > ^
    if afps.length = 1 then empty
    else actualParamsNextstate0(afps.tail)
    endif
  endif
endif

```

The function *expandAgentFormalParams0* expands an <agent formal parameters> so that each <parameters of sort> contains only one <name>.

```

expandAgentFormalParams0(afps: <agent formal parameters>):<agent formal parameters> =def
  if afps = empty then empty
  else
    if afps.head.s-<parameters of sort>.s-<name>-seq.length = 1
      then afps.head
      else < afps.head.s-<aggregation kind>,
        mk-<parameters of sort>( < afps.head.s-<parameters of sort>.s-<name>-seq[1] >,
          afps.head.s-<parameters of sort>.s-<sort>) > ^
        expandAgentFormalParams0(< afps.head.s-<aggregation kind>,
          mk-<parameters of sort>( < afps.head.s-<parameters of sort>.s-<name>-seq.tail >,
            afps.head.s-<parameters of sort>.s-<sort>
          ) > )
      endif
    if afps.length = 1 then empty
    else expandAgentFormalParams0(mk-<agent formal parameters>(afps.tail))
    endif
  endif
endif

```

The function *validOutputSignalSet0* gets the complete output signal set of an <agent type definition> or an <agent definition>.

```

validOutputSignalSet0(d: <agent type definition> ∪ <agent definition>):SIGNAL0 =def
  d.localOutputSignalSet0 ∪ d.inheritedOutputSignalSet0

```

The function *localOutputSignalSet0* gets the local output signal set of an <agent type definition> or an <agent definition>.

```

localOutputSignalSet0(d: <agent type definition> ∪ <agent definition>):SIGNAL0 =def
  { sid ∈ SIGNAL0:
    (∃ gc ∈ <gate constraint>:
      (gc.parentAS0 ∈ <textual gate definition>) ∧ isDefinedIn0(gc.parentAS0, d) ∧
      (gc.direction0 = out) ∧ (sid ∈ signalSet0(gc.s-<signal list item>-seq))) ∨
    (∃ cp ∈ <channel path>:
      (cp.parentAS0 ∈ <channel definition>) ∧ isDefinedIn0(cp.parentAS0, d) ∧
      (cp.destination0.s-env ≠ undefined) ∧ (sid ∈ signalSet0(cp.s-<signal list item>-seq))) }

```

The function *inheritedOutputSignalSet0* gets the inherited output signal set of an <agent type definition> or an <agent definition>.

```

inheritedOutputSignalSet0(d: <agent type definition> ∪ <agent definition>): SIGNAL0 =def
  if d.specialization0 = undefined then ∅
  else d.specialization0.s-<type expression>.baseType0.validOutputSignalSet0
  endif

```

The function *inheritedAgentBody0* gets an inherited agent body (if any) of an <agent type definition>. If the agent type is not specialized the result is the undefined value. If the base type of the agent has an agent body this is returned, otherwise it returns the inherited agent body (if any) of the base type. Note that if the base type has an agent body and inherits an agent body, the two bodies are not merged.

```

inheritedAgentBody0 (atd: <system type definition> ∪ <block type definition> ∪ <process type definition>):
  <agent body> =def
  let specialization =
  (case atd of
    | <system type definition> then atd.s-<system type heading>
    | <block type definition> then atd.s-<block type heading>
    | <process type definition> then atd.s-<process type heading>
  endcase).s-<agent type additional heading>.s-<agent additional heading>.s-<specialization>
  in
  if specialization = undefined then undefined
  else
    let baseType = specialization.s-<type expression>.baseType0 in
    let baseTypeBody = baseType.s-<agent structure>.s-<agent body> in
    if baseTypeBody ≠ undefined then baseTypeBody
    else inheritedAgentBody0 (baseType)
    endif
    endlet // baseTypeBody
    endlet // baseType
  endif
  endlet // specialization

```

### F2.2.5.1.2 System type

#### Concrete syntax

```

<system type definition> ::
  <package use clause>* <system type heading> <agent structure>
<system type heading> :: <qualifier> <system><name> <agent type additional heading>

```

#### Conditions on concrete syntax

```

∀ fcp ∈ <formal context parameter>:
  (fcp.surroundingScopeUnit0 ∈ <system type definition>) ⇒
  (fcp ∉ <agent context parameter> ∪ <variable context parameter list> ∪ <timer context parameter list>)

```

A <formal context parameter> of <formal context parameters> of <agent type additional heading> of a <system type definition> shall not be an <agent context parameter>, <variable context parameter list> or <timer context parameter list>. See clause 8.1.1.2 *Concrete grammar* of [ITU-T Z.102].

```

¬(∃ fps ∈ <agent formal parameters>: fps.surroundingScopeUnit0 ∈ <system type definition>)

```

The <agent type additional heading> in a <system type definition> shall not include <agent formal parameters>. See clause 8.1.1.2 *Concrete grammar* of [ITU-T Z.101].

#### Mapping to abstract syntax

```

| <system type definition>(*, <system type heading>(*, name,
  <agent type additional heading>(*, *, <agent additional heading>(spec, params))),

endlet // entitiesSet

```

The implicitly defined interface for a state machine is defined in the same scope unit as the state machine that defined it: that is, inside the agent type. See clause 12.1.2 *Concrete grammar* of [ITU-T Z.101].

### F2.2.5.1.3 Block type

#### Concrete syntax

```

<block type definition> ::
  <package use clause>* <block type heading> <agent structure>

<block type heading> ::
  <type preamble> <qualifier> <block type<name> <agent type additional heading>

```

## Transformations

The special stopping condition property of `set_v` and `get_v` procedures mentioned below is covered by the dynamic semantics. The two text paragraphs following the transformation code are derived from clause 9.2 Model of [ITU-T Z.102]. The first paragraph is an outline of the transform, and the second paragraph gives the detail. The transform of block definition into a typebased block definition and a block type follows the pattern for transforming agent definitions and is given in clause F2.2.6.1.

```
atd = <agent type definition>(packages,

```

A block with a global variable definition (a <variable definition> as an <entity in agent> in the <agent structure> of the block/system type of the block/system) has a state machine that is interpreted concurrently with agents in the block/system. Access from contained agents in the block/system to a global variable of the block is covered by two implicitly defined remote procedures for setting and getting the data item associated with the variable. These procedures are provided by the state machine of the block.

A block type *bt* with global variables is transformed by moving the global variables (each <variable definition> as an <entity in agent>) from the <agent structure> of *bt* to a new (anonymously named) state type *st1* for *bt* that replaces the existing state type *st* for the state machine of *bt*. The state type *st1* has a <specialization> "inherits *st* adding", and adds each <variable definition> deleted from the <agent structure> of *bt* to a <composite state type definition> of *st1*. For each variable *v* in *b*, *st1* has two exported procedures with anonymous implicit names, but here are called *set\_v* (with an **in**-parameter of the sort of *v*) and *get\_v* (with a return type being the sort of *v*). Each assignment to *v* from enclosed definitions of *bt* is transformed to a remote call of *set\_v*. Each occurrence of *v* in expressions in enclosed definitions is transformed to a remote call of *get\_v*. These occurrences also apply to occurrences in procedures defined in *bt*, as these are transformed into procedures local to the calling agents. There is no ambiguity between the remote procedure calls for different instances block type *bt*, because each instance has implicit remote procedure definitions for both procedures. The *set\_v* and *get\_v* procedures have a special property that means they are handled in the stopping condition of instances of *bt*. This transformation takes place after replacing agent definitions with typebased agent definitions and transforming context parameters, and before the transforming of remote procedures.

endlet // entitiesSet

```

## Auxiliary functions

The function *otherPartsComplete1* determines the Boolean expression of the *Continuous-Signal* for the partition of a state aggregation node that consume otherwise unused signals, given a list (blist) of identifiers for Boolean variables each of which indicates that the partition with the same name has completed.

```

otherPartsComplete1(blist: Identifier*): Operation-application =def
let andOpId = mk-Identifier(
  < mk-Package-qualifier(mk-Name("Predefined")), mk-Data-type-qualifier (mk-Name("Boolean")) >,
  mk-Name("and"))
in
if blist.length = 1 then mk-Operation-application(andOpId, < blist[1], true >)
else mk-Operation-application(andOpId, < blist.head, otherPartsComplete1(blist.tail) >)
endif
endlet // andOpId

```

## F2.2.5.2 Type expression

### Concrete syntax

```

<type expression> :: <base type> <actual context parameter list>
<base type> = <identifier>

```

### Conditions on concrete syntax

```

∀te ∈ <type expression>:
  te.actualContextParameterList0 ≠ empty ⇒ isParameterizedType0(te.baseType0)

```

It is valid to have <actual context parameters> if and only if <base type> denotes a parameterized type. See clause 8.1.2 *Concrete grammar* of [ITU-T Z.102].

### Transformations

```

te.anonymousTypeName
provided
te ∈ <type expression> ∧
te.s-<actual context parameter>-seq ≠ empty ∧
te.parentAS0 ∉ <specialization> ∧
te.anonymousTypeName = undefined
=11=>
(anonymousTypeName\{( te, undefined )} ) ∪ {( te, newName)}

te=<type expression>(id, params)
provided
te.s-<actual context parameter>-seq ≠ empty ∧
te.parentAS0 ∉ <specialization> ∧
te.anonymousTypeName ≠ undefined
=11=>
mk-<type expression>(
  mk-<identifier>(te.surroundingQualifier0,
    te.anonymousTypeName),
  empty)
and
te.surroundingScopeUnit0.getEntities0 // entities in nearest surrounding scope unit
=>
let basetype = id.refersto0 in
let fcpl = basetype.FormalContextParameterList0 in
te.surroundingScopeUnit0.getEntities0 ^
  < replaceContextParameters0(fcpl, params,
    createNewType0(te.anonymousTypeName, basetype,
      getUnboundFormalContextParameterList0(fcpl, params) ) ) >
endlet // fcpl
endlet // basetype

```

A <type expression> yields either the type identified by the identifier of <base type> in cases where there are no actual context parameters or an anonymous type defined by applying the actual context parameters to the formal context parameters of the parameterized type denoted by the identifier of <base type>. See clause 8.1.2 *Model* of [ITU-T Z.102].

## Mapping to abstract syntax

| <type expression>(x, *undefined*) **then** *Mapping*(x)

## Auxiliary functions

The function *anonymousTypeName* is used to store the name of the anonymous type created by applying actual context parameters to a base type of a type expression.

**controlled** *anonymousTypeName*: <type expression> → <name>  
**initially**  $\forall te \in \langle \text{type expression} \rangle: te.\text{anonymousTypeName} = \text{undefined}$

The function *isDirectSubType0* determines if a type definition is a direct subtype of an entity definition.

*isDirectSubType0*(*ed*: ENTITYDEFINITION0, *td*: TYPEDEFINITION0): BOOLEAN =<sub>def</sub>  
 $\exists te \in \langle \text{type expression} \rangle: te.\text{parentAS0} = ed.\text{specialization0} \wedge td = te.\text{baseType0}$

The function *isSubtype0* determines if a type definition is a subtype of an entity definition.

*isSubtype0*(*sub*: ENTITYDEFINITION0, *sup*: TYPEDEFINITION0): BOOLEAN =<sub>def</sub>  
*isDirectSubType0*(*sub*, *sup*)  $\vee$   
( $\exists ttd \in \text{TYPEDEFINITION0} : \text{isSubtype0}(\text{sub}, \text{ttd}) \wedge \text{isSubtype0}(\text{ttd}, \text{sup})$ )

The function *baseType0* is used to get the base type definition for a type expression.

*baseType0*(*te*: <type expression>): TYPEDEFINITION0 =<sub>def</sub>  
**let** *bt* = *te*.s-<identifier> **in**  
  *getEntityDefinition0*(*bt*, *idKind0*(*bt*))  
**endlet**

The function *isParameterizedType0* is used to determine if a type definition is a parameterized type.

*isParameterizedType0*(*td*: TYPEDEFINITION0): BOOLEAN =<sub>def</sub>  
(*td*.*formalContextParameterList0* ≠ *empty*)

Get the formal context parameter list of a type definition.

*formalContextParameterList0*(*td*: TYPEDEFINITION0): <formal context parameter>\* =<sub>def</sub>  
*td*.*inheritedFormalContextParameterList0*  $\hat{\cup}$  *td*.*localFormalContextParameterList0*

Get the formal context parameter list of the super type of a type definition.

*inheritedFormalContextParameterList0*(*td*: TYPEDEFINITION0): <formal context parameter>\* =<sub>def</sub>  
**let** *sp* = *td*.*specialization0* **in**  
  **if** *sp* = *undefined* **then** *empty* **else**  
    **case** *sp* **of**  
      | <interface specialization> **then**  
        < *getUnboundFormalContextParameterList0*(*tel*.*baseType0*.*formalContextParameterList0*,  
          *tel*.*actualContextParameterList0*)  
        | *tel* **in** *sp*.s-<type expression>-**seq** >  
      **otherwise**  
        **let** *fcpl* = *sp*.s-<type expression>.baseType0.*formalContextParameterList0* **in**  
        **let** *acpl* = *sp*.s-<type expression>.actualContextParameterList0 **in**  
          *getUnboundFormalContextParameterList0*(*fcpl*, *acpl*)  
        **endlet** // *acpl*  
        **endlet** // *fcpl*  
      **endcase**  
    **endif**  
  **endlet** // *sp*

Get the unbound formal context parameter list of a formal context parameter list according to an actual context parameter list.

```

getUnboundFormalContextParameterList0(fcpl: <formal context parameter>*,
  acpl: <actual context parameter>*): <formal context parameter>* =def
  if (fcpl = empty) then empty
  else
    if (acpl.head = undefined) then <fcpl.head> else empty endif
    ^getUnboundFormalContextParameterList0(fcpl.tail, acpl.tail)
  endif

```

The function *completeFormalContextParameter0* inserts the <identifier> for the original formal context parameter for the unbound ones.

```

completeFormalContextParameter0(fcpl: <name>*, acpl: <actual context parameter list>):
  <actual context parameter list> =def
  if (fcpl = empty) then empty
  else
    if (acpl.head = undefined) then <mk-<identifier>(undefined, fcpl.head)> else <acpl.head> endif
    ^completeFormalContextParameter0(fcpl.tail, acpl.tail)
  endif

```

The function *actualContextParameterList0* gets the actual context parameter list of a type expression. Each item in the list corresponds to [ <actual context parameter> ]; that is, the item is either *undefined* or an <actual context parameter>.

```

actualContextParameterList0(te: <type expression>): <actual context parameter list> =def
  te.s-<actual context parameter list>

```

Get the formal context parameter list local to a type definition.

```

localFormalContextParameterList0(td: TYPEDEFINITION0): <formal context parameter>* =def
  let fcps = take({fcps ∈ <agent type additional heading> ∪ <composite state type heading> ∪
    <procedure heading> ∪ <signal definition> ∪ <data type heading> ∪
    <interface heading>: fcps.s.surroundingScopeUnit0 = td}) in
    <fcpl.formalContextParameterSublist0 | fcpl in fcps.s-<formal context parameter>-seq >
  endlet

```

Expand a formal context parameter to a list of formal context parameters so that each item in the list contains just one name.

```

formalContextParameterSublist0(fcp: <formal context parameter>): <formal context parameter>* =def
  case fcp of
  | <agent context parameter> then <fcp >
  | <agent type context parameter> then <fcp >
  | <compositestate type context parameter> then <fcp >

otherwise undefined
endcase

```

### F2.2.5.3 Definitions based on types

#### Concrete syntax

```

<textual typebased agent definition> =
  <textual typebased system definition>
  | <textual typebased block definition>
  | <textual typebased process definition>

```

#### Conditions on concrete syntax

$$\forall ad \in \langle \text{textual typebased agent definition} \rangle: \forall te \in \langle \text{type expression} \rangle: \\ (te.parentAS0.parentAS0 = ad) \Rightarrow \\ (\exists s \in \langle \text{start} \rangle: (s \in te.baseType0.startSet0) \wedge (s.s-\langle \text{name} \rangle = \text{undefined}))$$

The agent type denoted by <base type> in the type expression of a <textual typebased agent definition> shall contain an unlabelled start transition in its state machine. See clause 9 *Concrete grammar* of [ITU-T Z.101].

#### F2.2.5.3.1 System definition based on system type

##### Concrete syntax

```

<textual typebased system definition>::
  <typebased system heading>

<typebased system heading> ::
  <system<name> <system<type expression>

```

##### Mapping to abstract syntax

```

| <textual typebased system definition>( <typebased system heading>(name, <type expression>(b, *))) then
  mk-Agent-definition(Mapping(name), mk-Number-of-instances(1,1,0), Mapping(b))

```

#### F2.2.5.3.2 Block definition based on block type

##### Concrete syntax

```

<textual typebased block definition> ::
  <typebased block heading>

<typebased block heading> ::
  <block<name> <number of instances> <block<type expression>

```

## Mapping to abstract syntax

| <textual typebased block definition>  
(<typebased block heading>(name, inst, <type expression>(b,\*)) **then**  
**mk-Agent-definition**(Mapping(name), Mapping(inst), Mapping(b))

### F2.2.5.3.3 Process definition based on process type

#### Concrete syntax

<textual typebased process definition> = <typebased process heading>  
<typebased process heading> ::  
<process><name> <number of instances> <process><type expression>

#### Mapping to abstract syntax

| <textual typebased process definition> (name, inst, <type expression>(b,\*)) **then**  
**mk-Agent-definition**(Mapping(name), Mapping(inst), Mapping(b))

### F2.2.5.3.4 Composite state definition based on composite state type

#### Concrete syntax

<typebased composite state> ::  
<composite state><name> <nextstate parameters> <composite state><type expression>  
<textual typebased state partition def> =  
<typebased state partition heading>  
<typebased state partition heading> :: <composite state><name> <composite state><type expression>

#### Mapping to abstract syntax

A composite state based on a type is mapped within the production for states.

### F2.2.5.4 Abstract type

#### Abstract syntax

*Abstract* :: {}

#### Concrete syntax

<abstract> :: ()

#### Conditions on concrete syntax

$\forall pd \in \langle \text{procedure definition} \rangle: isAbstractType0(pd) \Rightarrow$   
 $\neg(\exists pc \in \langle \text{procedure call} \rangle: pd = pc.calledProcedure0)$

An abstract procedure shall not be called.

NOTE 1 – The above text is derived from "An abstract type shall not be instantiated" (see below); a procedure is a type and calling a procedure instantiates the procedure.

$\forall ad \in \langle \text{textual typebased agent definition} \rangle: \forall te \in \langle \text{type expression} \rangle:$   
 $te.parentAS0.parentAS0 = ad \Rightarrow \neg isAbstractType0(te.baseType0)$

A typebased agent shall not be specified with an abstract agent type as the type.

NOTE 2 – The above text is derived from "An abstract type shall not be instantiated" (see below); a typebased agent is an instantiation of the agent type.

$\forall td \in \langle \text{TYPEDEFINITION0} \rangle: isAbstractType0(td) \Rightarrow$   
 $\neg(\exists d \in \langle \text{textual typebased agent definition} \rangle \cup \langle \text{textual typebased state partition def} \rangle \cup$   
 $\langle \text{typebased composite state} \rangle: \exists te \in \langle \text{type expression} \rangle:$   
 $((te.parentAS0.parentAS0 = d) \vee (te.parentAS0 = d)) \wedge (te.baseType0 = td))$

An abstract type shall not be instantiated. See clause 8.1.3 *Semantics* of [ITU-T Z.102].

NOTE 3 – The abstract property of a type is not inherited; therefore instantiation of a subtype of an abstract data type is permitted, if the subtype is not itself abstract.

## Mapping to abstract syntax

| <abstract> **then** *Abstract*

## Auxiliary functions

Determine if a type definition is abstract, either because it is defined as abstract by the keyword **abstract** or because it has unbound context parameters.

```
isAbstractType0(td: TYPEDEFINITION0): BOOLEAN =def
  (∃ab ∈ <abstract>: ab.surroundingScopeUnit0 = td)
  ∨ (∃te ∈ <type expression>: te.surroundingScopeUnit0 = td ∧
    getUnboundFormalContextParameterList0(te.baseType0, formalContextParameterList0,
      te.actualContextParameterList0) ≠ empty)
```

Get the <internal procedure definition> denoted by a <procedure call>.

```
calledProcedure0(pc: <procedure call> ∪ <value returning procedure call>
  ∪ <procedure call body> ∪ <remote procedure call body>):
  <procedure definition> =def
  case pc of
  | <procedure call> ∪ <value returning procedure call> then
    let t = pc.s-<procedure call body>.s-implicit in
      if t ∈ <identifier> then getEntityDefinition0(t, procedure)
      else t.baseType0 // t ∈ <type expression>
    endlet // t
  | <procedure call body> then
    let t = pc.s-implicit in
      t.baseType0 // t ∈ <type expression>
    endlet // t
  | <remote procedure call body> then getEntityDefinition0(pc, remote procedure)
  otherwise undefined
endcase
```

### F2.2.5.5 Type reference

Type references do not have semantics in SDL-2010.

### F2.2.5.6 Gate

#### Abstract syntax

```
Gate-definition          ::      Gate-name
                           [ Encoding-rules ]
                           In-signal-identifier-set
                           Out-signal-identifier-set
```

```
In-signal-identifier    =      Signal-identifier
```

```
Out-signal-identifier   =      Signal-identifier
```

∀gd ∈ Gate-definition:

```
let supertype = gd.parentAS1.baseType1 in
  supertype = undefined
```

```
∨ (∀stgd ∈ (supertype.s-Gate-definition-set):
  (((gd.s-Gate-name = stgd.s-Gate-name) ∧ (stgd.s-Encoding-rules ≠ undefined))
  ⇒ (gd.s-Encoding-rules = stgd.s-Encoding-rules))
endlet // supertypeid
```

The *Encoding-rules* associated with a *Gate-definition* of a type based on a supertype shall specify the same set of *Encoding-rules* as the *Encoding-rules* of the corresponding gate definition in the supertype if that gate has *Encoding-rules*.

## Concrete syntax

<gate in definition> = <textual gate definition> | <textual interface gate definition>  
 <textual gate definition> ::  
     <gate> [ <encoding rules> ] <gate constraint>  
 <textual interface gate definition> ::  
     { **out** | **in** } <interface-identifier> [ <encoding rules> ] [ <textual endpoint constraint> ]  
 <gate> = <gate><name>  
 <gate constraint> ::  
     **in** [ <textual endpoint constraint> ] [ <signal list> ]  
         [ **out** [ <textual endpoint constraint> ] [ <signal list> ] ]  
     | [ **out** [ <textual endpoint constraint> ] [ <signal list> ] ]  
 <textual endpoint constraint> :: [ **atleast** ] <identifier>  
 <as gate> :: <gate><identifier>

NOTE 1 – The derived AS0 for any SDL/PR <gate constraint> with **out** followed by **in** is the AS0 <gate constraint> with **in** followed by **out**.

## Conditions on concrete syntax

NOTE 2 – In the concrete graphical grammar clause 8.1.4 *Concrete grammar* of [ITU-T Z.102], the <textual endpoint constraint> of a <gate definition> is enclosed by a <block symbol> or <process symbol> or <state symbol>, and the <identifier> of the <textual endpoint constraint> has to denote the type for a block or process or state (respectively) depending on the symbol. In textual grammar (SDL/PR and AS0), there is no keyword or other construct equivalent to the <block symbol> or <process symbol> or <state symbol>, and therefore no requirement for the <identifier> of the <textual endpoint constraint> to denote specifically the type of a block or process or state.

$$\begin{aligned}
 \forall gc \in \langle \text{gate constraint} \rangle : & (\forall ce \in \langle \text{channel endpoint} \rangle : (\forall ce1 \in \langle \text{channel endpoint} \rangle : ( \\
 & (gc.parentAS0.s-\langle \text{gate} \rangle = ce.s-\langle \text{gate} \rangle) \wedge \\
 & (ce \neq ce1) \wedge (ce.parentAS0 = ce1.parentAS0) \wedge (ce.parentAS0 \in \langle \text{channel path} \rangle) \wedge \\
 & (gc.parentAS0 \in \langle \text{textual gate definition} \rangle)) \Rightarrow \\
 & ( \text{let } td = \text{getEntityDefinition0}(gc.s-\langle \text{textual endpoint constraint} \rangle, \\
 & \quad gc.surroundingScopeUnit0.entityKind0) \text{ in} \\
 & \quad \exists td1 \in ENTITYDEFINITION0: \\
 & \quad \quad ((td1 = ce1.channelEndPointReferTo0) \wedge ((td = td1) \vee isSubtype0(td1, td))) \\
 & \text{endlet}) \wedge \\
 & (ce.parentAS0.s-\langle \text{signal list item} \rangle\text{-seq.signalSet0} \subseteq gc.s-\langle \text{signal list item} \rangle\text{-seq.signalSet0})
 \end{aligned}$$

A channel connected to a gate shall be compatible with the endpoint constraint of the gate. A channel is compatible with this constraint if the other endpoint of the channel is an agent or state of the type denoted by <identifier> in the endpoint constraint or (in case it contains a <textual endpoint constraint> with **atleast**) a subtype of this type, and if the set of signals (if specified) on the channel is equal to, or is a subset of, the set of signals specified for the gate in the respective direction. See clause 8.1.4 *Concrete grammar* of [ITU-T Z.102].

$$\begin{aligned}
 \forall tbd \in \langle \text{textual typebased block definition} \rangle \cup \langle \text{textual typebased process definition} \rangle : \\
 \forall te \in \langle \text{type expression} \rangle : & (te.parentAS0.parentAS0 = tbd) \Rightarrow \\
 & (\text{let } td = te.baseType0 \text{ in} \\
 & \quad (td.channelDefinitionSet0 \neq \emptyset) \Rightarrow \\
 & \quad (\forall gc \in \langle \text{gate constraint} \rangle : \forall sig \in SIGNAL0: \\
 & \quad \quad (gc.parentAS0 \in td.gateDefinitionSet0) \\
 & \quad \quad \wedge (sig \in gc.s-\langle \text{signal list item} \rangle\text{-seq.signalSet0}) \\
 & \quad \quad \Rightarrow (\exists cp \in \langle \text{channel path} \rangle : \\
 & \quad \quad \quad (cp.parentAS0 \in td.channelDefinitionSet0) \\
 & \quad \quad \quad \wedge \\
 & \quad \quad \quad ((gc.direction0 = \text{in}) \Rightarrow \\
 & \quad \quad \quad \quad (cp.Origination0.s-\langle \text{gate} \rangle = gc.parentAS0.s-\langle \text{gate} \rangle) \wedge \\
 & \quad \quad \quad \quad (cp.Origination0.s-implicit = \text{env}))
 \end{aligned}$$

```

)
^
((gc.direction0=out)⇒
  (cp.destination0.s-<gate> = gc.parentAS0.s-<gate>) ∧
  (cp.destination0.s-implicit = env)
)
^
(sig∈cp.s-<signal list item>-seq.signalSet0)
)
)
endlet)

```

The following two text paragraphs reference the condition formalized above. The domain *SIGNAL0* includes signals, remote procedures and remote variables.

If the type denoted by <base type> in a <textual typebased block definition> or <textual typebased process definition> contains channels, the following rule applies: for each combination of a gate, a signal and the direction of the <signal list> of the gate defined by the type, the type shall contain at least one channel that – for the given direction – mentions **env** and the gate and mentions the signal (or has no explicit <signal list> associated if [ITU-T Z.103] is being applied to allow the <signal list area> to be omitted). Modified from clause 8.1.4 *Concrete grammar* of [ITU-T Z.101] to apply to AS0.

If the type denoted by <base type> in a <textual typebased block definition> or <textual typebased process definition> contains channels, the following rule applies: for each combination of a gate, a remote procedure (or remote variable) and the direction of the <signal list> of the gate defined by the type, the type shall contain at least one channel that – for the given direction – mentions **env** for this gate and mentions the remote procedure or remote variable, respectively (or has no explicit <signal list area> associated if [ITU-T Z.103] is being applied to allow the <signal list area> to be omitted). Modified from clause 8.1.4 *Concrete grammar* of [ITU-T Z.102] to apply to AS0.

$$\forall gc, gc1 \in \langle \text{gate constraint} \rangle:$$

$$(gc \neq gc1) \wedge (gc.parentAS0 = gc1.parentAS0) \Rightarrow$$

$$(gc.s-\langle \text{textual endpoint constraint} \rangle = gc1.s-\langle \text{textual endpoint constraint} \rangle) \wedge$$

$$((gc.direction0=**out**) \wedge (gc1.direction0=**in**)) \vee ((gc.direction0=**in**) \wedge (gc1.direction0=**out**))$$

Where both **in** and **out** are specified in a <gate constraint>, this is for a bidirectional gate, and if two <textual endpoint constraint>s are given, they shall be the same. See clause 8.3.12 *Concrete grammar* of [ITU-T Z.102].

$$\forall gd \in \langle \text{textual gate definition} \rangle: (gd.s-\langle \text{adding} \rangle \neq \text{undefined}) \Rightarrow$$

$$(\text{let } td = gd.surroundingScopeUnit0 \text{ in}$$

$$\exists td1 \in \text{TYPEDEFINITION0} : \exists gd1 \in \langle \text{textual gate definition} \rangle:$$

$$isSubtype0(td, td1) \wedge (gd1 \in td1.gateDefinitionSet0) \wedge$$

$$(gd1.s-\langle \text{gate} \rangle = gd.s-\langle \text{gate} \rangle)$$

$$\text{endlet})$$

It is only allowed to specify **adding** in a subtype definition and only for a gate defined in the supertype. See clause 5.4.1.3 of [ITU-T Z.106].

$$\forall ec, ec1 \in \langle \text{textual endpoint constraint} \rangle:$$

$$isSubtype0(ec.surroundingScopeUnit0, ec1.surroundingScopeUnit0) \wedge$$

$$(ec.parentAS0 \in \langle \text{gate constraint} \rangle) \wedge (ec1.parentAS0 \in \langle \text{gate constraint} \rangle) \wedge$$

$$(ec.parentAS0.parentAS0 \in \langle \text{textual gate definition} \rangle) \wedge$$

$$(ec1.parentAS0.parentAS0 \in \langle \text{textual gate definition} \rangle) \wedge$$

$$(ec.parentAS0.parentAS0.s-\langle \text{adding} \rangle \neq \text{undefined}) \wedge$$

$$(((ec.direction0=**out**) \wedge (ec1.direction0=**in**)) \vee ((ec.direction0=**in**) \wedge (ec1.direction0=**out**))) \wedge$$

$$(ec.parentAS0.parentAS0.s-\langle \text{gate} \rangle = ec1.parentAS0.parentAS0.s-\langle \text{gate} \rangle) \Rightarrow$$

$$(\text{let } td = getEntityDefinition0(ec.s-\langle \text{identifier} \rangle, ec.surroundingScopeUnit0.entityKind0) \text{ in}$$

$$\text{let } td1 = getEntityDefinition0(ec1.s-\langle \text{identifier} \rangle, ec1.surroundingScopeUnit0.entityKind0) \text{ in}$$

$$(td = td1) \vee isSubtype0(td, td1)$$

```

endlet // td1
endlet // td

```

If <textual endpoint constraint> is specified for the gate in the supertype, the <identifier> of an (added) <textual endpoint constraint> shall denote the same type or a subtype of the type denoted in the <textual endpoint constraint> of the supertype. See clause 8.1.4 *Concrete grammar* of [ITU-T Z.102].

## Transformations

```

<textual interface gate definition>(out, id=<identifier>(*,n))
=8=>
mk-<textual gate definition>(n, undefined, mk-<gate constraint>(out, undefined, id))

```

```

<textual interface gate definition>(in, id=<identifier>(*,n))
=8=>
mk-<textual gate definition>(n, undefined, mk-<gate constraint>(in, undefined, id))

```

<textual interface gate definition> is shorthand for a <textual gate definition> having the name of the interface as <gate name> and the <interface identifier> as the <signal list>. See clause 8.1.4 *Model* of [ITU-T Z.103].

```

gd.asGateName
provided
  gd ∈ <textual gate definition>
  ∧ gd.asGateName = undefined
=8=>
(asGateName \{( gd, undefined )\} ) ∪ \{( gd, newName )\}

```

NOTE 1 – Each <textual gate definition> defines a *Data-type-definition* of a choice data type with a unique anonymous *Sort* name stored in *asGateName*: see Note 2 below.

```

<as gate>(gid)
provided
  gid.refersto0.asGateName ≠ undefined
=8=>
mk-<type expression>(mk-<identifier>(gid.s-<qualifier>, gid.refersto0.asGateName), undefined)

```

An <as gate> represents the sort of the choice data type introduced by the identified gate definition. See clause 12.1 *Concrete grammar* of [ITU-T Z.104].

## Mapping to abstract syntax

```

| tgd = <textual gate definition>(name, *,
  <gate constraint>(in, *, inlist, out, *, outlist) ) then
mk-Gate-definition(
  Mapping(name),
  Mapping(encodingRules0(tgd)),
  { Mapping(inlist[i]): i ∈ 1..inlist.length },
  { Mapping(outlist[i]): i ∈ 1..outlist.length })

```

```

| tgd = <textual gate definition>(name, *,
  <gate constraint>(in, *, inlist, undefined,*,*) ) then
mk-Gate-definition(
  Mapping(name),
  Mapping(encodingRules0(tgd)),
  { Mapping(inlist[i]): i ∈ 1..inlist.length,
  ∅)

```

```

| tgd = <textual gate definition>(name, *,
  <gate constraint>(out, *, outlist) ) then
mk-Gate-definition(

```

*Mapping(name)*,  
*Mapping(encodingRules0(tgd))*,  
 $\emptyset$ ,  
 { *Mapping(outlist[i])*:  $i \in 1..outlist.length$  }

If there is no set of <encoding rules> that is associated with a <textual gate definition> of a type based on a supertype, and there is a set of *Encoding-rules* for the gate in the supertype, the inherited gate has this set of *Encoding-rules*. If there is no set of *Encoding-rules* for the gate in the supertype, the presence and value of the inherited gate *Encoding-rules* is determined by the presence and value of the <encoding rules>. See clause 8.1.4 *Concrete grammar* of [ITU-T Z.104].

NOTE 2 – The mapping to a *Data-type-definition* for the choice data type defined by a <textual gate definition> in the following paragraph takes place by invoking the function *choiceForGate1* (defined below), in the mapping to *Agent-type-definition* in clauses F2.2.5.1.2, F2.2.5.1.3 and F2.2.5.1.4, or in the mapping of a <composite state type definition> with a <composite state structure> to a *Composite-state-type-definition* in clause F2.2.5.1.5.

A <textual gate definition> defines a *Data-type-definition* of a choice data type with a unique anonymous *Sort* name in the context that the *Gate-definition* is visible. A <basic sort> that is <as gate> where <gate identifier> identifies the *Gate-definition* represents this *Data-type-definition*. The *Data-type-definition* is equivalent to defining a choice data type with a <choice of sort> for each distinct *Signal-definition* identified by the *In-signal-identifier-set* and *Out-signal-identifier-set*. Each <choice of sort> has as its <field sort> the data type denoted by <as signal> for the identified signal definition (the `NULL` sort for a signal without parameters; otherwise a structure data type with an anonymous unique name – for an identified signal `signal_id` with parameters the <choice of sort> has a <field sort> with identity as denoted by `as signal signal_id`). If an identified *Signal-definition* has a name distinct from any other identified distinct *Signal-definition*, the <choice of sort> has the same <field name> as the name of the corresponding identified signal. If an identified *Signal-definition* has the same name as another identified *Signal-definition*, the <choice of sort> has <field name> with the same name as the anonymous unique name for the <as signal> structure data type. See clause 8.1.4 *Concrete grammar* of [ITU-T Z.104].

## Auxiliary functions

The function *origination0* gets the originating channel endpoint of a <channel path>.

*origination0*(*p*: <channel path>): <channel endpoint> =<sub>def</sub>  
*p.s*-<channel endpoint>

The function *destination0* gets the destination channel endpoint of a <channel path>.

*destination0*(*p*: <channel path>): <channel endpoint> =<sub>def</sub>  
*p.s2*-<channel endpoint>

The function *gateDefinitionSet0* gets the <gate in definition>-set defined in an <agent type definition>, a <composite state type definition>, a <agent definition> or a <composite state definition>.

*gateDefinitionSet0*(*td*: <agent type definition>  $\cup$  <composite state type definition>  $\cup$   
 <agent definition>  $\cup$  <composite state definition> ): <gate in definition>-set =<sub>def</sub>  
*td.localGateDefinitionSet0*  $\cup$  *td.inheritedGateDefinitonSet0*

The function *localGateDefinitionSet0* gets the <gate in definition>-set defined by the <gate in definition> items of an <agent type definition>, a <composite state type definition>, a <agent definition> or a <composite state definition>.

*localGateDefinitionSet0*(*td*: <agent type definition>  $\cup$  <composite state type definition>  $\cup$   
 <agent definition>  $\cup$  <composite state definition> ): <gate in definition>-set =<sub>def</sub>  
 { *gd*  $\in$  <gate in definition>: *gd.surroundingScopeUnit0* = *td* }

The function *inheritedGateDefinitonSet0* gets the <gate in definition>-**set** inherited by an <agent type definition>, a <composite state type definition>, a <agent definition> or a <composite state definition>.

```

inheritedGateDefinitonSet0(td: <agent type definition> ∪ <composite state type definition> ∪
  <agent definition> ∪ <composite state definition> ): <gate in definition>-set =def
let sp=td.specialization0 in
  if sp=undefined then ∅
  else sp.s-<type expression>.baseType0.gateDefinitionSet0
  endif
endlet

```

The function *encodingRules0* determines the <encoding rules> item to be used for the mapping from a <textual gate definition> to a *Gate-definition*.

```

encodingRules0(tgd: <textual gate definition>): <encoding rules> =def
if tgd.s-<encoding rules> ≠ undefined then tgd.s-<encoding rules>
else
let stgates =
  inheritedGateDefinitonSet0(
    parentAS0ofKind(tgd,
      <agent type definition> ∪ <composite state type definition> ∪ <agent definition> ∪ <composite state
      definition>))
  in
    if stgates = ∅ then undefined
    else
      if (∃ stgd ∈ stgates: ((tgd.s-<name> = stgd.s-<name>) ∧ (stgd.s-<encoding rules> ≠ undefined))
      then
        take(stgd ∈ stgates: tgd.s-<name> = stgd.s-<name>).s-<encoding rules>
      else undefined
      endif
    endif
  endlet
endif

```

The function *channelDefinitionSet0* gets the <channel definition> items defined in an <agent type definition> or an <agent definition>.

```

channelDefinitionSet0(td: <agent type definition> ∪ <agent definition> ): <channel definition>-set =def
  td.localChannelDefinitionSet0 ∪ td.inheritedChannelDefinitionSet0

```

The function *localChannelDefinitionSet0* gets the <channel definition> items defined locally (rather than inherited) in an <agent type definition> or an <agent definition>.

```

localChannelDefinitionSet0(td: <agent type definition> ∪ <agent definition> ):
  <channel definition>-set =def
  {cd ∈ <channel definition>: cd.surroundingScopeUnit0 = td}

```

The function *inheritedChannelDefinitionSet0* gets the <channel definition> items defined inherited by an <agent type definition> or an <agent definition>.

```

inheritedChannelDefinitionSet0(td: <agent type definition> ∪ <agent definition> ):
  <channel definition>-set =def
  let sp=td.specialization0 in
    if sp=undefined then ∅
    else sp.s-<type expression>.baseType0.channelDefinitionSet0
    endif
  endlet // sp

```

The function *signalSet0* produces the set of identifiers for entities of kind **signal**, **timer**, **remote procedure** or **remote variable** (that is, of domain *SIGNAL0*) for the given <signal list item> list. A

<signal list item> of kind **signal**, **timer**, **remote procedure** or **remote variable** has its identifier included in the set. A <signal list item> of kind **interface** is expanded to include the identifiers of each <signal list item> defined and used by the interface.

```

signalSet0(sl:<signal list item>*) : SIGNAL0 =def
  case sl.head.idKind0 of
  | {signal, timer, remote procedure, remote variable} then {sl.head} ∪ sl.tail.signalSet0
  | {interface} then
    let id = getEntityDefinition0(sl.head, interface) in
      id.usedSignalSet0 ∪ {sd.identifier0 | sd ∈ id.definedSignalSet0} ∪ sl.tail.signalSet0
    endlet // id
  otherwise ∅
endcase

```

The function *choiceForGate1* produces the choice *Data-type-definition* that corresponds to a *Gate-definition* and is used when an <as gate> is given for a <basic sort>.

```

choiceForGate1(gd: <textual gate definition>): Data-type-definition =def
Mapping(mk-<data type definition>( mk-<type preamble>(undefined, undefined), // type preamble
  mk-<data type heading>( gd.asGateName, // name for choice type
    undefined, undefined, // no formal parameters or virtuality constraint
  ), // data type heading
  mk-<data type definition body>( empty, // no entities in data type
    mk-<choice definition>( undefined, // visibility
      < mk-<choice of sort>( undefined, // visibility
        mk-<field of kind>( part,
          if sig.s-<name> ∉ { othersigs.s-<name>
            : othersigs ∈ ((inoutSignals0(gd, in) ∪ inoutSignals0(gd, out)) \ sig )
          then // unique signal name
            sig.s-<name>
          else // not unique signal name – name same as <as signal>
            sig.asSignal.s-<name> // name of structure sort for signal
          endif
        ), // field of kind
        mk-<field sort>(
          if sig.refersto0.s-implicit // <sort list> | <named fields sort list> | <sort<identifier>
            = undefined // no sort
          then predefinedId0("NULL")
          else sig.asSignal // structure sort for signal
          endif
        ) // field sort
      ) // choice of sort item
      : sig ∈ (inoutSignals0(gd, in) ∪ inoutSignals0(gd, out))
    > // choice of sort> list
  ) // choice definition
  ), // data type definition body
  undefined // default initialization
)) // Mapping of data type definition

```

The function *asGateName* associates each <textual gate definition> with a unique anonymous name for the *Sort* of the corresponding *Data-type-definition* of the choice data type invoked by <as gate>.

```

controlled asGateName: <textual gate definition> → <name>
initially ∀ gd ∈ <textual gate definition>: gd.asGateName = undefined

```

The function *asGateName1* is used to make the data type *Identifier* for <as gate> available to F3.

```

asGateName1(id1: Identifier): Identifier // gate Identifier to sort Identifier
take({ Mapping(mk-<identifier>(q0, asGateName(id0))) :
  id0 = mk-<identifier>( q0, n0) ∧ id0.refersto0 ∈ <gate definition> ∧
  Mapping(q0) = id1.s-Qualifier ∧ Mapping(n0) = id1.s-Name })

```

## F2.2.5.7 Context parameters

### Concrete syntax

<actual context parameter list> = [ <actual context parameter> ]\*

<actual context parameter> :: <identifier> | <constant><primary>

<formal context parameters> = <formal context parameter list>

<formal context parameter list> :: <formal context parameter>+

<formal context parameter> =

- <agent context parameter>
- | <agent type context parameter>
- | <compositestate type context parameter>
- | <gate context parameter>
- | <interface context parameter list>
- | <procedure context parameter>
- | <remote procedure context parameter>
- | <remotevariable context parameter list>
- | <signal context parameter list>
- | <sort context parameter>
- | <synonym context parameter list>
- | <timer context parameter list>
- | <variable context parameter list>

### Conditions on concrete syntax

$$\forall fcp \in \text{FORMALCONTEXTPARAMETER0} : \forall acp \in \text{<actual context parameter>} : \\ \text{isContextParameterCorresponded0}(fcp, acp) \wedge (acp \in \text{<primary>}) \Rightarrow \\ (fcp \in \text{<synonym context parameter name>})$$

An <actual context parameter> shall not be a <constant><primary> unless it is for a synonym context parameter. See clause 8.3 *Concrete grammar* of [ITU-T Z.102].

$$(\forall te \in \text{<type expression>} : te.baseType0 \notin \text{FORMALCONTEXTPARAMETER0}) \wedge \\ (\forall fcp \in \text{FORMALCONTEXTPARAMETER0} : \\ fcp.contextParameterAtleastDefinition0 \notin \text{FORMALCONTEXTPARAMETER0})$$

Formal context parameters are not allowed to be used as <base type> in <type expression> or in **atleast** constraints of <formal context parameters>. See clause 8.3 *Concrete grammar* of [ITU-T Z.102].

$$\forall fcp \in \text{<agent type context parameter>} \cup \text{<agent context parameter>} \cup \text{<procedure context parameter>} \cup \\ \text{<signal context parameter name>} \cup \text{<sort context parameter>} \cup \\ \text{<compositestate type context parameter>} \cup \text{<interface context parameter name>} : \\ \forall acp \in \text{<actual context parameter>} : \text{isContextParameterCorresponded0}(fcp, acp) \Rightarrow \\ (\forall td1 \in \text{TYPEDEFINITION0} : (td1 = fcp.contextParameterAtleastDefinition0) \Rightarrow \\ (td1 \notin \text{FORMALCONTEXTPARAMETER0}) \wedge \neg(\text{isParameterizedType0}(td1)) \wedge \\ (\exists td \in \text{TYPEDEFINITION0} : \\ (td = \text{getEntityDefinition0}(acp, td1.entityKind0)) \wedge \\ ((td = td1) \vee \text{isSubtype0}(td, td1))))))$$

An **atleast** clause denotes that the formal context parameter shall be replaced by an actual context parameter, which is the same type or a subtype of the type identified in the **atleast** clause. Identifiers following the keyword **atleast** in this clause shall identify type definitions of the entity kind of the context parameter and shall be neither formal context parameters nor parameterized types. See clause 8.3 *Concrete grammar* of [ITU-T Z.102].

### Transformations

<formal context parameter list>(fcpl)  
**provided**  
fcpl.length < fcpl.expandFormalContextParams0.length

```
=11=>
mk-<formal context parameter list>( fcpl.expandFormalContextParams0)
```

The formal context parameter list is expanded so that each <formal context parameter> that is a list (<remotevariable context parameter list>, <signal context parameter list>, <synonym context parameter list>, <timer context parameter list> or <variable context parameter list>) contains only one named parameter.

```
<composite state type heading>( v, q, n, cPar, vc,
  <specialization>( <type expression>( base, actPar)), p)
provided
  getUnboundFormalContextParameterList0
  ( actParams, base.refersto0.s-<formal context parameter>) ≠ empty
=11=>
  ( let nCPar = cPar ^
    getUnboundFormalContextParameterList0
    ( actParams, base.refersto0.s-<formal context parameter>)
  in
    let nActPar =
      completeFormalContextParameter0( actParams, base.refersto0.s-<formal context parameter>)
    in
      mk-<composite state type heading>
        ( v, q, n, nCPar, vc, <specialization>( <type expression>( b, nActPar)), p)
    endlet
  endlet)
```

```
<agent type additional heading>( cPar, vc,
  <agent additional heading>( <specialization>( <type expression>( base, actPar)), p)
provided

    ( actParams, base.refersto0.s-<formal context parameter>)
  in
    let nActPar =
      completeFormalContextParameter0( actParams, base.refersto0.s-<formal context parameter>)
    in
      mk-<agent type additional heading>( nCPar, vc,
        mk-<agent additional heading>
          ( mk-<specialization>( mk-<type expression>( base, nActPar, undefined), p))
      endlet // nActPar
      endlet // nCPar
  )
```

```
<procedure heading>( v, q, n, cPar, vc, <specialization>( <type expression>( base, actPar)), p, r, x)
provided
  getUnboundFormalContextParameterList0
  ( actParams, base.refersto0.s-<formal context parameter>)
  ≠ empty
=11=>
  ( let nCPar = cPar ^
    getUnboundFormalContextParameterList0
    ( actParams, base.refersto0.s-<formal context parameter>)
  in
    let nActPar =
      completeFormalContextParameter0( actParams, base.refersto0.s-<formal context parameter>)
    in
      mk-<procedure heading>( v, q, n, nCPar, vc,
        mk-<specialization>( mk-<type expression>( b, nActPar, undefined), p, r, x)
      endlet // nActPar
```

```

    endlet // nCPar
)

<signal definition>(n, cPar, vc, <specialization>( <type expression>(base, actPar)), p)
provided
    getUnboundFormalContextParameterList0
        (actParams, base.refersto0.s-<formal context parameter>) ≠ empty
=11=>
( let nCPar = cPar ^
    getUnboundFormalContextParameterList0
        (actParams, base.refersto0.s-<formal context parameter>)
in
    let nActPar =
        completeFormalContextParameter0(actParams, base.refersto0.s-<formal context parameter>)
in
    <signal definition>
        (n, nCPar, vc, <specialization>( <type expression>(b, nActPar), undefined*), p)
    endlet // nActPar
    endlet // nCPar
)

```

If the scope unit contains <specialization> and any <actual context parameter> items are omitted in the <type expression>, the <formal context parameter>s are copied (while preserving their order) and inserted in front of the <formal context parameter>s (if any) of the scope unit. In place of omitted <actual context parameter>s, the names of corresponding <formal context parameter>s are inserted. These <actual context parameter> items now have the defining context in the current scope unit.

### Auxiliary functions

Expand a <formal context parameter> list so that each <formal context parameter> that is a list (<remotevariable context parameter list>, <signal context parameter list>, <synonym context parameter list>, <timer context parameter list> or <variable context parameter list>) contains only one named parameter.

```

expandFormalContextParams0(fcpl: <formal context parameter>+): <formal context parameter>+ =def
< fcpl.head >.formalContextParameterSublist0 ^
if fcpl.length = 1
then <>
else fcpl.tail.expandFormalContextParams0
endif

```

Get the entity definition referred by the formal context parameter constraint.

```

contextParameterAtleastDefinition0(fcp: FORMALCONTEXTPARAMETER0): ENTITYDEFINITION0 =def
case fcp of
| <agent type context parameter> then
    if (fcp.s-<agent type constraint> ∈ <identifier>) then
        getEntityDefinition0(fcp.s-<agent type constraint>.<identifier>, agent type)
    else undefined
    endif
| <agent context parameter> then
    if (fcp.s-<agent constraint> ∈ <agent constraint atleast>) then
        getEntityDefinition0(fcp.s-<agent constraint>.s-<identifier>, agent type)
    else if (fcp.s-<agent constraint> ∈ <agent constraint exactly>) then
        getEntityDefinition0(fcp.s-<agent constraint>.s-<identifier>, agent type)
    else undefined
    endif
endif
| <procedure context parameter> then
    if (fcp.s-<procedure constraint> ∈ <identifier>) then
        getEntityDefinition0(fcp.s-<procedure constraint>, procedure)
    else undefined

```

```

endif
| <compositestate type context parameter> then
  if (fcps-<composite state type constraint>∈<identifier>) then
    getEntityDefinition0(fcps-<composite state type constraint>,
      state type)
  else undefined
  endif
| <signal context parameter name> then
  if (fcps-<signal constraint>∈<identifier>) then
    getEntityDefinition0(fcps-<signal constraint>, signal)
  else undefined
  endif
| <sort context parameter> then
  if (fcps-<sort constraint>∈<sort>) then
    getEntityDefinition0(fcps-<sort constraint>, type)
  else undefined
  endif
| <interface context parameter name> then
  if (fcps-<interface constraint> ≠ undefined) then
    getEntityDefinition0(fcps-<interface constraint>.s-<identifier>, interface)
  else undefined
  endif
otherwise undefined
endcase

```

### F2.2.5.7.1 Agent type context parameter

#### Concrete syntax

```

<agent type context parameter> ::
  <agent kind> <agent type><name> [<agent type constraint>]

<agent kind> :: process | block

<agent type constraint> =
  <agent type><identifier> | <agent signature>

```

#### Conditions on concrete syntax

```

∀fcps∈<agent type context parameter>:∀acps∈<actual context parameter>:
  isContextParameterCorresponded0(fcps, acps) ∧ (fcps-<agent type constraint> ≠ undefined) ⇒
  (let td=getEntityDefinition0(acps, agent type) in
  let pl = td.agentFormalParameterList0 in
  let sl = fcps-<agent type constraint>.agentSignatureSortList0 in
    (∃td1∈<agent type definition>: // subtype of the constraint agent type
      (
        (td1=fcps.contextParameterAtleastDefinition0)
        ∧ (td.agentLocalFormalParameterList0=empty)
        ∧ isSubtype0(td,td1)
      )
    )
  )
  ∨ // agent type definition compatible with formal agent signature
  (
    (td.entityKind0 = fcps.entityKind0) ∧ (pl.length = sl.length)
    ∧ (∀i∈1..pl.length: isSameSort0(pl[i].parentAS0.s-<sort>, sl[i]))
  )
  )
endlet // sl
endlet // pl
endlet // td

```

An actual agent type parameter shall be a subtype of the constraint agent type (**atleast** <agent type identifier>) with no addition of formal parameters to those of the constraint type, or has to be compatible with the formal agent signature. See clause 8.3.1 *Concrete grammar* of [ITU-T Z.102].

An agent type definition is compatible with the formal agent signature if it has the same kind and if the formal parameters of the agent type definition have the same sorts as the corresponding <sort>s of the <agent signature>. See clause 8.3.1 *Concrete grammar* of [ITU-T Z.102].

### Auxiliary functions

Get the sort list defined in an <agent signature>.

```
agentSignatureSortList0(as: <agent signature>):<sort>* =def
as.s-<sort>-seq
```

Get the formal parameter list of an <agent type definition>, an <agent definition>, a <composite state type definition> or a <composite state definition>.

```
agentFormalParameterList0(td: <agent type definition> ∪ <agent definition> ∪
<composite state type definition> ∪ <composite state definition> ): <name>* =def
td.agentLocalFormalParameterList0 ∪ td.agentInheritedFormalParameterList0
```

```
agentLocalFormalParameterList0(td: <agent type definition> ∪ <agent definition> ∪
<composite state type definition> ∪ <composite state definition> ): <name>* =def
let fp=take({fp∈ <agent additional heading> ∪
<composite state type heading> ∪
<composite state heading>:
fp.surroundingScopeUnit0 = td}) in
if (fp.s-<agent formal parameters>= undefined)
then empty
else <psl.s-<name> | psl in fp.s-<agent formal parameters>.s-<parameters of sort>-seq >
endif
endlet
```

```
agentInheritedFormalParameterList0(td: <agent type definition> ∪ <agent definition> ∪
<composite state type definition> ∪ <composite state definition> ): <name>* =def
let sp=td.specialization0 in
if (sp = undefined) then empty
else sp.s-<type expression>.baseType0.agentFormalParameterList0
endif
endlet
```

Determine if a formal context parameter corresponds to an actual context parameter; that is, the position of the formal context parameter in the list of inherited and local formal context parameters for the base type of the type expression containing the actual context parameter is the same as the position of the actual context parameter in the list of actual context parameters.

NOTE – The actual context parameter list is allowed to be shorter than the formal parameter list when items are omitted from the end of the list.

```
isContextParameterCorresponded0( fcp: FORMALCONTEXTPARAMETER0,
acp: <actual context parameter>): BOOLEAN =def
let te = parentAS0ofKind(acp, <type expression>) in
let fcpl = te.baseType0.formalContextParameterList0 in
let acpl = te.actualContextParameterList0 in
(fcpl.length ≥ acpl.length) ∧
(∃!i∈1..acpl.length: (fcpl[i]=fcp) ∧ (acpl[i]=acp))
endlet // acpl
endlet // fcpl
endlet // te
```

### F2.2.5.7.2 Agent context parameter

#### Concrete syntax

```
<agent context parameter> ::
<agent kind> <agent-name> [<agent constraint>]
```

<agent constraint> = <agent constraint atleast> | <agent constraint exactly> | <agent signature>  
 <agent constraint atleast> :: <agent type<identifier>  
 <agent constraint exactly> :: <agent type<identifier>  
 <agent signature> :: <sort list>

## Conditions on concrete syntax

```

∀fcp∈<agent context parameter>: ∀acp∈<actual context parameter>:
( isContextParameterCorresponded0(fcp, acp) ⇒ (
  let ad = getEntityDefinition0(acp, fcp.s-<agent kind>) in // agent def for acp
  let atda = // agent type def for acp
    if fcp.s-<agent kind> = block then
      then acp.refersto0.s-<typebased block heading>.s-<type expression>.baseType0
    else acp.refersto0.s-<typebased process heading>.s-<type expression>.baseType0
    endif
  in
  let atdf = fcp.contextParameterAtleastDefinition0 in // atleast agent type def for fcp
  ad ≠ undefined // acp has of same kind (block/process) as fcp
  ^
  ((fcp.s-<agent constraint> ∈ <agent constraint atleast>) ⇒
    isSubtype0(atda, atdf) ∧ (atda.agentLocalFormalParameterList0 = empty))
  ^
  ((fcp.s-<agent constraint> ∈ <agent constraint exactly>) ⇒ (atda = atdf))
  ^
  ((fcp.s-<agent constraint> ∈ <agent signature>) ⇒
    ( let pl = atda.agentFormalParameterList0 in
      let sl = fcp.s-<agent constraint>.agentSignatureSortList0 in
      (pl.length = sl.length) ∧ (∀i∈1..pl.length: isSameSort0(pl[i].parentAS0.s-<sort>, sl[i]))
      endlet // sl
      endlet // pl
    )
    endlet // atdf
    endlet // atda
    endlet // ad
  ) // fcp and acp correspond
) for all acp
  
```

An actual agent parameter shall identify a block definition if the <agent kind> is **block** in the <agent context parameter>; otherwise it shall specify a process definition. Modified ("**block** is specified" changed to "the <agent kind> is **block**") from clause 8.3.2 *Concrete grammar* of [ITU-T Z.102].

In the case of <agent constraint atleast>, the actual agent type shall be the same as, or a subtype of, the constraint agent type with no addition of formal parameters to those of the constraint type. Modified ("**atleast** <agent type identifier> constraint" changed to "<agent constraint atleast>") from clause 8.3.2 *Concrete grammar* of [ITU-T Z.102].

In the case of an <agent constraint exactly>, the actual agent type shall be the type denoted by <agent type<identifier>. Modified ("a <colon> <agent type identifier> constraint" changed to "an <agent constraint exactly>") from clause 8.3.2 *Concrete grammar* of [ITU-T Z.102].

In the case of an <agent signature> constraint, the actual agent shall be compatible with the <agent signature>. An agent definition is compatible with the <agent signature> if the formal parameters of the agent definition have the same aggregation kind and sorts as the corresponding elements of the <agent signature>, and both definitions have the same *Agent-kind*. See clause 8.3.2 *Concrete grammar* of [ITU-T Z.102].

### F2.2.5.7.3 Procedure context parameter

#### Concrete syntax

<procedure context parameter> ::

<procedure><name> <procedure constraint>  
 <procedure constraint> =  
 <procedure><identifier> | <procedure signature>

## Conditions on concrete syntax

```

 $\forall fcp \in \langle \text{procedure context parameter} \rangle : \forall acp \in \langle \text{actual context parameter} \rangle :$ 
  isContextParameterCorresponded0(fcp, acp)  $\Rightarrow$ 
    (let pda = getEntityDefinition0(acp, procedure) in // procedure def for acp
      ((fcp.s-<procedure constraint>  $\in$  <identifier>)  $\Rightarrow$  // at least case
        isDirectSubType0(pda, fcp.contextParameterAtleastDefinition0))
      ^
      ((fcp.s-<procedure constraint>  $\in$  <procedure signature>)  $\Rightarrow$  // signature case
        ( let resulta = pda.s-<procedure heading>.s-<procedure result> in
          let resultf = fcp.s-<procedure constraint>.s-<result> in
            ((resulta = undefined)  $\wedge$  (resultf = undefined))  $\vee$ 
            ((resulta  $\neq$  undefined)  $\wedge$  (resultf  $\neq$  undefined)  $\wedge$  isSameResult0(resulta, resultf))
          endlet // resultf
          endlet // resulta
        ) // both have same result or no result
      ^
      ( let fpla = pd.procedureFormalParameterList0 in
        let fplf = fcp.s-<procedure constraint>.s-<formal parameter>-seq in
          (fpla.length = fplf.length)
          ^
          ( $\forall i \in 1..fpla.length :$ 
            ((fpl[i].parentAS0.parentAS0.s-<parameter kind> = fplf[i].s-<parameter kind>)
            ^
            (fpla[i].parentAS0.parentAS0.s-<parameter kind>  $\in$  {in out, out}))  $\Rightarrow$ 
            isSameSort0(fpla[i].parentAS0.s-<sort>, fplf[i].s-<sort>)
          endlet // fplf
          endlet // fpla
        ) // for all items in the parameter lists
      ) // covering case (a) and (b)
    endlet) // endlet pda, implication for corresponding parameters
  
```

The following text paragraphs are from clause 8.3.3 *Concrete grammar* of [ITU-T Z.102]. In the AS0 <procedure constraint>, **atleast** <procedure identifier> is the <procedure><identifier> alternative and <procedure signature in constraint> is the <procedure signature> alternative.

In the case of **atleast** <procedure identifier>, an actual procedure parameter shall identify a procedure definition that is the same as or a specialization of the procedure of the constraint.

In the case of <procedure signature in constraint>, an actual procedure parameter shall identify a procedure definition compatible with the formal procedure signature given by <procedure signature in constraint>.

A procedure definition is compatible with the formal procedure signature if both have a result of the same <sort> or if neither returns a result, and:

- a) the formal parameters of the procedure definition have the same sorts as the corresponding parameters of the signature each with the same <parameter kind>; or
- b) each **in/out** and **out** parameter in the procedure definition has the same <sort identifier> or <syntype identifier> as the corresponding parameter of the signature.

### F2.2.5.7.4 Remote procedure context parameter

#### Concrete syntax

<remote procedure context parameter>::  
 <remote procedure><name> <procedure signature>

## Conditions on concrete syntax

```
∀fcp∈<remote procedure context parameter>: ∀acp∈<actual context parameter>:  
isContextParameterCorresponded0(fcp,acp) ⇒  
  ( isSameProcedureSignature0(  
    getEntityDefinition0(acp, remote procedure).s-<procedure signature>,  
    fcp.s-<procedure signature>)  
  )
```

An actual parameter to a **remote** procedure context parameter shall identify a <remote procedure definition> compatible with formal procedure signature given by <procedure signature in constraint>. See clause 8.3.4 *Concrete grammar* of [ITU-T Z.102], and <procedure signature in constraint> is <procedure signature> in AS0.

## Auxiliary functions

Determine if two <procedure signature>s are the same.

```
isSameProcedureSignature0(ps, ps1: <procedure signature>): BOOLEAN =def  
  let fpl = ps.procedureSignatureParameterList0 in  
  let fpl1 = ps1.procedureSignatureParameterList0 in  
  (fpl.length = fpl1.length) ∧  
  (∀i∈1..fpl.length:  
    isSameSort0(fpl[i].s-<sort>, fpl1[i].s-<sort>) ∧  
    (fpl[i].s-<parameter kind> = fpl1[i].s-<parameter kind>)) ∧  
  isSameResult0(ps.s-<result>, ps1.s-<result>))  
endlet  
endlet
```

### F2.2.5.7.5 Signal context parameter

#### Concrete syntax

```
<signal context parameter list> :: <signal context parameter name>+  
<signal context parameter name> :: <signal<name> [<signal constraint>]  
<signal constraint> = <signal<identifier> | <signal signature>  
<signal signature> = <sort list>
```

#### Conditions on concrete syntax

```
∀fcp∈<signal context parameter name>: ∀acp∈<actual context parameter>:  
isContextParameterCorresponded0(fcp, acp) ⇒  
  ( let sd = getEntityDefinition0(acp, signal) in  
    ((fcp.s-<signal constraint>∈<identifier>) ⇒  
      isSubtype0(sd, fcp.contextParameterAtleastDefinition0 )  
    )  
    ^  
    ((fcp.s-<signal constraint>∈<signal signature>) ⇒  
      isSameSortList0(sd.s-<sort>-seq, fcp.s-<signal constraint>)  
    )  
  )  
endlet // sd  
)
```

In the case of **atleast** <signal identifier>, an actual signal parameter shall identify a signal definition that is the same as, or a subtype of, the signal type of the constraint. In the case of <signal signature>, an actual signal parameter shall identify a signal definition that is compatible with the formal <signal signature>. A signal definition is compatible with the formal <signal signature> if each parameter of the signal definition has the same aggregation kind and sort as the corresponding parameter of the <signal signature>. See clause 8.3.5 *Concrete grammar* of [ITU-T Z.102].

### F2.2.5.7.6 Variable context parameter

#### Concrete syntax

<variable context parameter list> :: <variable context parameter names>+  
<variable context parameter names> :: <variable<name>+ <variable constraint>  
<variable constraint> = <sort>

#### Conditions on concrete syntax

$\forall fcp \in \langle \text{name} \rangle: \forall acp \in \langle \text{actual context parameter} \rangle:$   
( $fcp.parentAS0 \in \langle \text{variable context parameter names} \rangle$ )  $\wedge$   
( $fcp.parentAS0.parentAS0 \in \langle \text{variable context parameter list} \rangle$ )  $\wedge$   
 $isContextParameterCorresponded0(fcp, acp) \Rightarrow$   
( $isSameSort0(fcp.parentAS0.s-\langle \text{sort} \rangle, getEntityDefinition0(acp, \text{variable}).s-\langle \text{sort} \rangle)$ )

An actual parameter shall be a variable or a formal agent or procedure parameter of the same sort as the sort of the variable context parameter. See clause 8.3.6 *Concrete grammar* of [ITU-T Z.102].

### F2.2.5.7.7 Remote variable context parameter

#### Concrete syntax

<remotevariable context parameter list> ::  
<remotevariable contextparameter names>+  
<remotevariable contextparameter names> ::  
<remote variable<name>+ <variable constraint>

#### Conditions on concrete syntax

$\forall fcp \in \text{FORMALCONTEXTPARAMETER0}: \forall acp \in \langle \text{actual context parameter} \rangle:$   
( $fcp.parentAS0 \in \langle \text{remotevariable contextparameter names} \rangle$ )  $\wedge$   
( $fcp.parentAS0.parentAS0 \in \langle \text{remotevariable context parameter list} \rangle$ )  $\wedge$   
 $isContextParameterCorresponded0(fcp, acp) \Rightarrow$   
( $isSameSort0(fcp.parentAS0.s-\langle \text{sort} \rangle, getEntityDefinition0(acp, \text{remote variable}).s-\langle \text{sort} \rangle)$ )

An actual parameter shall identify a <remote variable definition> of the same sort as the sort of the remote variable context parameter. See clause 8.3.7 *Concrete grammar* of [ITU-T Z.102].

### F2.2.5.7.8 Timer context parameter

#### Concrete syntax

<timer context parameter list> :: <timer context parameter name>+  
<timer context parameter name> :: <timer<name> [<timer constraint>]  
<timer constraint> = <sort list>

#### Conditions on concrete syntax

$\forall fcp \in \langle \text{timer context parameter name} \rangle: \forall acp \in \langle \text{actual context parameter} \rangle:$   
 $isContextParameterCorresponded0(fcp, acp) \Rightarrow$   
( $fcp.s-\langle \text{timer constraint} \rangle \neq \text{undefined}$ )  $\Rightarrow$   
 $isSameSortList0(fcp.s-\langle \text{timer constraint} \rangle, getEntityDefinition0(acp, \text{timer}).s-\langle \text{sort} \rangle-\text{seq})$

An actual timer parameter shall identify a timer definition that is compatible with the formal sort constraint list. A timer definition is compatible with a formal sort constraint list if the sorts of the timer are the same sorts as in the sort constraint list. See clause 8.3.8 *Concrete grammar* of [ITU-T Z.102].

### F2.2.5.7.9 Synonym context parameter

#### Concrete syntax

<synonym context parameter list> ::

<synonym context parameter name>+  
 <synonym context parameter name> ::  
     <synonym<name> <synonym constraint>  
 <synonym constraint> = <sort>

### Conditions on concrete syntax

$\forall fcp \in \langle \text{synonym context parameter name} \rangle: \forall acp \in \langle \text{actual context parameter} \rangle:$   
 $isContextParameterCorresponded0(fcp, acp) \Rightarrow$   
 $isSameSort0(acp.staticSort0, fcp.s-\langle \text{synonym constraint} \rangle)$

An actual synonym parameter shall be a constant expression of the same sort as the sort of the constraint. See clause 8.3.9 *Concrete grammar* of [ITU-T Z.102].

### F2.2.5.7.10 Sort context parameter

#### Concrete syntax

<sort context parameter> :: <sort<name> [<sort constraint>]  
 <sort constraint> = <sort> | <sort signature>  
 <sort signature> ::  
     <literal signature>\* <operation signature>\* <operation signature>\*

#### Conditions on concrete syntax

$\forall fcp \in \langle \text{sort context parameter} \rangle: \forall acp \in \langle \text{actual context parameter} \rangle:$   
 $isContextParameterCorresponded0(fcp, acp) \wedge (fcp.s-\langle \text{sort constraint} \rangle \neq \text{undefined}) \Rightarrow$   
 ( **let**  $td = getEntityDefinition0(acp, \mathbf{type}).derivedDataType0$  **in**  
      $((fcp.s-\langle \text{sort constraint} \rangle \in \langle \text{sort} \rangle) \Rightarrow$   
          $((td.s-\langle \text{data type specialization} \rangle.s-\langle \text{renaming} \rangle = \text{undefined}) \wedge$   
              $isSubtype0(td, fcp.contextParameterAtleastDefinition0))$   
     )  
      $\wedge$   
      $((fcp.s-\langle \text{sort constraint} \rangle \in \langle \text{sort signature} \rangle) \Rightarrow$   
          $(\forall ls \in \langle \text{literal signature} \rangle: (ls.parentAS0 = fcp.s-\langle \text{sort constraint} \rangle) \Rightarrow$   
              $\exists ls1 \in \langle \text{literal signature} \rangle:$   
                  $(ls1.surroundingScopeUnit0 = td) \wedge isSameLiteralSignature0(ls, ls1)) \wedge$   
                  $(\forall os \in \langle \text{operation signature} \rangle:$   
                      $(os.parentAS0 = fcp.s-\langle \text{sort constraint} \rangle) \Rightarrow$   
                          $\exists os1 \in \langle \text{operation signature} \rangle:$   
                              $(os1.parentAS0 \in \langle \text{operator list} \rangle \cup \langle \text{method list} \rangle) \wedge$   
                              $(os1.surroundingScopeUnit0 = td) \wedge isSameOperationSignature0(os, os1))$   
                 )  
     )  
     **endlet** // td  
 )

In the case of a <sort constraint> that is **atleast** <sort>, an actual sort parameter shall be the sort given by <sort> or a subtype (without renaming) of this sort. In the case of a <sort constraint> that is <sort signature>, an actual sort parameter shall be compatible with the formal sort signature. A sort is compatible with the formal sort signature if the literals of the sort include the literals in the formal sort signature, and the operations defined by the data type that introduced the sort include the operations in the formal sort signature and the operations have the same signatures. See clause 8.3.10 *Concrete grammar* of [ITU-T Z.102].

$\forall ls \in \langle \text{literal signature} \rangle:$   
 $(ls.parentAS0 \in \langle \text{sort signature} \rangle) \wedge (ls.parentAS0.parentAS0 \in \langle \text{sort context parameter} \rangle) \Rightarrow$   
 $(ls \notin \langle \text{named number} \rangle)$

The <literal signature> of the <sort signature> shall not contain <named number>. See clause 8.3.10 *Concrete grammar* of [ITU-T Z.102].

## Auxiliary functions

Get the data type definition from which a syntype definition is derived.

```
derivedDataType0(sd: <syntype definition> ∪ <data type definition>): <data type definition> =def  
if (sd ∈ <syntype definition>) then sd.parentDataType0  
else sd  
endif
```

Get the parent data type definition of a syntype definition.

```
parentDataType0(sd: <syntype definition>): <data type definition> =def  
if (sd.s-<parent sort identifier> = undefined) then sd  
else  
  let pd = getEntityDefinition0(sd.s-<parent sort identifier>, type) in  
  if (pd ∈ <data type definition>) then pd  
  else pd.parentDataType0  
  endif  
endlet  
endif
```

Determine if two <literal signature>s are the same.

```
isSameLiteralSignature0(ls: <literal signature>, lsI: <literal signature>): BOOLEAN =def  
(ls ∈ <literal name>) ∧ (lsI ∈ <literal name>) ⇒ (ls = lsI) ∧  
(ls ∈ <named number>) ∧ (lsI ∈ <named number>) ⇒  
(ls.s-<literal name> = lsI.s-<literal name>) ∧  
(ls.s-<simple expression>.value0 = lsI.s-<simple expression>.value0)
```

Determine if two <operation signature>s are the same.

```
isSameOperationSignature0(os: <operation signature>, osI: <operation signature>): BOOLEAN =def  
(os.virtuality0 = osI.virtuality0) ∧  
(os.visibility0 = osI.visibility0) ∧  
(os.s-implicit ∈ <operation name> ⇒ os.s-implicit = osI.s-implicit) ∧  
(let fpl = os.operationSignatureParameterList0,  
  fplI = osI.operationSignatureParameterList0 in  
(fpl.length = fplI.length) ∧  
(∀ i ∈ 1..fpl.length:  
  (fpl[i].s-<parameter kind> = fplI[i].s-<parameter kind>) ∧  
  (isSameSort0(fpl[i].s-<sort>, fplI[i].s-<sort>)) ∧  
  (isSameResult0(os.s-<result>, osI.s-<result>))  
endlet)
```

### F2.2.5.7.11 Composite state context parameter

#### Concrete syntax

```
<compositestate type context parameter>::  
  <composite state type><name> [<composite state type constraint>]  
<composite state type constraint> =  
  <composite state type><identifier> | <composite state type signature>  
<composite state type signature> = <sort list>
```

#### Conditions on concrete syntax

```
∀ fcp ∈ <compositestate type context parameter>: ∀ acp ∈ <actual context parameter>:  
isContextParameterCorresponded0(fcp, acp) ∧  
(fcp.s-<composite state type constraint> ≠ undefined) ⇒  
( let td = getEntityDefinition0(acp, state type) in  
((fcp.s-<composite state type constraint> ∈ <identifier>) ⇒  
(td.agentLocalFormalParameterList0 = empty) ∧  
  isSubtype0(td, fcp.contextParameterAtleastDefinition0))
```

```

)
^
((fcp.s-<composite state type constraint>∈<composite state type signature>) ⇒
  (
    let sl = fcp.s-<composite state type constraint> in
    let pl = td.agentFormalParameterList0 in
    (sl.length = pl.length) ∧
    (∀i∈1..sl.length: isSameSort0(sl[i], pl[i].parentAS0.s-<sort>))
    endlet // pl
    endlet // sl
  )
)
endlet // td
)

```

The following text paragraphs are from clause 8.3.11 *Concrete grammar* of [ITU-T Z.102].

An actual composite state type parameter shall identify a composite state type definition.

In the case of a <composite state type constraint> that is **atleast** <composite state type identifier>, the actual composite state type shall be the same or a subtype of the constraint composite state type <composite state type identifier>, with no addition of formal parameters to those of the constraint type.

In the case of a <composite state type constraint> that is a <composite state type signature>, the actual composite state type shall be compatible with the formal composite state type signature. A composite state type definition is compatible with the formal composite state type signature if each formal parameter to the composite state type definition has the same aggregation kind and sort as the corresponding parameter of the <composite state type constraint>.

#### F2.2.5.7.12 Gate context parameter

##### Concrete syntax

<gate context parameter> :: <gate> <gate constraint>

##### Conditions on concrete syntax

```

∀fcp∈<gate context parameter>:∀acp∈<actual context parameter>:
  isContextParameterCorresponded0(fcp, acp) ⇒
  (
    let gd=getEntityDefinition0(acp, gate) in
    (gd.s-<gate> = fcp.s-<gate>) ∧
    (∀gc∈<gate constraint>:∀gc1∈<gate constraint>:
      (gc.parentAS0 = gd) ∧ (gc1.parentAS0 = fcp) ∧
      ((gc.direction0 = out) ∧ (gc1.direction0 = out) ⇒
        gc1.s-<sort>-seq.signalSet0 ⊆ gc.s-<sort>-seq.signalSet0)
      ∧
      ((gc.direction0=in) ∧ (gc1.direction0=in) ⇒
        gc.s-<sort>-seq.signalSet0 ⊆ gc1.s-<sort>-seq.signalSet0)
      endlet // gd
    )
  )

```

An actual gate parameter shall identify a gate definition. The outward signal list of the actual gate parameter shall contain all elements mentioned **with** <signal list> of the corresponding **out** formal gate context parameter. The **in** formal gate context parameter shall mention **with** <signal list> all inward elements of the actual gate parameter. See clause 8.3.12 *Concrete grammar* of [ITU-T Z.102].

#### F2.2.5.7.13 Interface context parameter

##### Concrete syntax

<interface context parameter list> :: <interface context parameter name>+

<interface context parameter name> :: <interface name> [<interface constraint>]

<interface constraint> :: <interface identifier>

## Conditions on concrete syntax

$\forall fcp \in \langle \text{interface context parameter name} \rangle: \forall acp \in \langle \text{actual context parameter} \rangle:$   
 $isContextParameterCorresponded0(fcp, acp) \wedge (fcp.s-\langle \text{interface constraint} \rangle \neq \text{undefined}) \Rightarrow$   
 $(\exists td \in \langle \text{interface definition} \rangle:$   
 $(td = getEntityDefinition0(acp.s-\langle \text{identifier} \rangle, \text{interface})) \wedge$   
 $isSubtype0(td, fcp.contextParameterAtleastDefinition0))$

An actual interface parameter shall identify an interface definition. In the case of an <interface constraint>, the type of the interface shall be the same or a subtype of the interface type identified by **atleast** <interface identifier>. See clause 8.3.13 *Concrete grammar* of [ITU-T Z.102].

## F2.2.5.8 Specialization

### F2.2.5.8.1 Adding properties

#### Concrete syntax

<specialization> :: <type expression>

#### Mapping to abstract syntax

| <specialization>(x) **then** Mapping(x)

#### Auxiliary functions

The function *specialization0* is used to get the specialization part of an entity definition.

*specialization0*(def: ENTITYDEFINITION0):  
 $\langle \text{specialization} \rangle \cup \langle \text{data type specialization} \rangle \cup \langle \text{interface specialization} \rangle =_{\text{def}}$   
 $take(\{ s \in \langle \text{specialization} \rangle \cup \langle \text{data type specialization} \rangle \cup \langle \text{interface specialization} \rangle:$   
 $s.surroundingScopeUnit0 = \text{def} \})$

### F2.2.5.8.2 Virtual type

#### Concrete syntax

<virtuality> = **virtual** | **redefined** | **finalized**

<virtuality constraint> :: <identifier>

#### Conditions on concrete syntax

The text paragraphs below are from clause 8.4.2 *Concrete grammar* of [ITU-T Z.102].

$\forall td \in \langle \text{block type definition} \rangle \cup \langle \text{process type definition} \rangle \cup \langle \text{procedure definition} \rangle \cup$   
 $\langle \text{composite state type definition} \rangle:$   
 $isVirtualType0(td) \Rightarrow td.virtualTypeAtleastDefinition0.entityKind0 = td.entityKind0$

Every virtual type has associated a virtuality constraint which is an <identifier> of the same entity kind as the virtual type.

$\forall td \in \langle \text{block type definition} \rangle \cup \langle \text{process type definition} \rangle \cup \langle \text{procedure definition} \rangle \cup$   
 $\langle \text{composite state type definition} \rangle:$   
 $td.isVirtualType0 \Rightarrow$   
 $\neg(td.isParameterizedType0) \wedge \neg(isParameterizedType0(td.virtualTypeAtleastDefinition0))$

A virtual type and its constraints shall not have context parameters.

$\forall vc \in \langle \text{virtuality constraint} \rangle: isVirtualType0(vc.surroundingScopeUnit0)$

Only virtual types are allowed to have <virtuality constraint> specified.

$\forall r \in \langle \text{block type reference} \rangle \cup \langle \text{process type reference} \rangle \cup \langle \text{composite state type reference} \rangle \cup$   
 $\langle \text{procedure reference} \rangle:$   
 $\forall d \in \langle \text{block type definition} \rangle \cup \langle \text{process type definition} \rangle \cup \langle \text{composite state type definition} \rangle \cup$

<procedure definition>:  
 $(r.referencedDefinition0 = d) \wedge (r.virtuality0 \neq undefined) \wedge (d.virtuality0 \neq undefined) \Rightarrow$   
 $(r.virtuality0 = d.virtuality0)$

If <virtuality> is present in both a definition reference and the referenced definition, they shall be the same.

$\forall r \in \text{procedure reference}: \forall d \in \text{procedure definition}:$   
 $( ( r.referencedDefinition0 = d )$   
 $\wedge ( ( r.s-\langle \text{procedure reference heading} \rangle.s-\langle \text{type preamble} \rangle.s-\text{implicit} \neq undefined)$   
 $\vee ( r.s-\langle \text{procedure reference heading} \rangle.s-\langle \text{exported} \rangle \neq undefined ) ) // \text{proc preamble in reference}$   
 $\wedge ( ( d.s-\langle \text{procedure heading} \rangle.s-\langle \text{type preamble} \rangle.s-\text{implicit} \neq undefined)$   
 $\vee ( d.s-\langle \text{procedure heading} \rangle.s-\langle \text{exported} \rangle \neq undefined ) ) // \text{proc preamble in referenced proc}$   
 $) \Rightarrow // \text{ref and definition both have "proc preamble", therefore preamble/export the same}$   
 $( ( r.s-\langle \text{procedure reference heading} \rangle.s-\langle \text{type preamble} \rangle =$   
 $d.s-\langle \text{procedure heading} \rangle.s-\langle \text{type preamble} \rangle)$   
 $\wedge ( r.s-\langle \text{procedure reference heading} \rangle.s-\langle \text{exported} \rangle = d.s-\langle \text{procedure heading} \rangle.s-\langle \text{exported} \rangle)$   
 $)$

If <procedure preamble> is present in both procedure reference and in the referenced procedure definition they shall be the same.

$\forall td \in \langle \text{block type definition} \rangle \cup \langle \text{process type definition} \rangle: isVirtualType0(td) \Rightarrow$   
 $( \text{let } td1 = td.virtualTypeAtleastDefinition0 \text{ in}$   
 $isSameAgentFormalParameterList0(td.agentFormalParameterList0,$   
 $td1.agentFormalParameterList0)$   
 $\wedge$   
 $(\forall gd1 \in \langle \text{gate in definition} \rangle: gd1 \in td1.gateDefinitionSet0 \Rightarrow$   
 $\exists gd \in \langle \text{gate in definition} \rangle: (gd \in td.gateDefinitionSet0) \wedge isSameGate0(gd, gd1))$   
 $\wedge$   
 $(\forall fd1 \in \langle \text{interface definition} \rangle: fd1 \in td1.interfaceDefinitionSet0 \Rightarrow$   
 $\exists fd \in \langle \text{interface definition} \rangle: (fd \in td.interfaceDefinitionSet0) \wedge isSameInterface0(fd, fd1))$   
 $\wedge$   
 $(\forall ed \in ENTITYDEFINITION0: ed.surroundingScopeUnit0 = td \Rightarrow$   
 $\exists ed1 \in ENTITYDEFINITION0: (ed1.surroundingScopeUnit0 = td1) \wedge (ed = ed1))$   
 $\text{endlet // td1}$   
 $)$

A virtual agent type shall have exactly the same formal parameters, and at least the same gates and interfaces with at least the definitions as those of its constraint.

$\forall td \in \langle \text{composite state type definition} \rangle: isVirtualType0(td) \Rightarrow$   
 $(\text{let } td1 = td.virtualTypeAtleastDefinition0 \text{ in}$   
 $\forall scp1 \in \langle \text{state connection points} \rangle: scp1 \in td1.stateConnectionPointSet0 \Rightarrow$   
 $\exists scp \in \langle \text{state connection points} \rangle:$   
 $(scp \in td.stateConnectionPointSet0) \wedge isSameStateConnectionPoint0(scp, scp1) \text{ endlet})$

A virtual state type shall have exactly the same formal parameters, and at least the same state connection points as its constraint.

$\forall td \in \langle \text{procedure definition} \rangle: isVirtualType0(td) \Rightarrow$   
 $isSameProcedureFormalParameterList0($   
 $td.procedureFormalParameterList0,$   
 $td.virtualTypeAtleastDefinition0.procedureFormalParameterList0$   
 $)$

A virtual procedure shall have exactly the same formal parameters as its constraint.

$\forall td \in \langle \text{block type definition} \rangle \cup \langle \text{process type definition} \rangle \cup \langle \text{procedure definition} \rangle \cup$   
 $\langle \text{composite state type definition} \rangle:$   
 $isVirtualType0(td) \Rightarrow$   
 $(\forall sp \in \langle \text{specialization} \rangle: \forall vc \in \langle \text{virtuality constraint} \rangle:$   
 $(sp.surroundingScopeUnit0 = td) \wedge (vc.surroundingScopeUnit0 = td) \Rightarrow$   
 $((td.virtualTypeInheritsDefinition0 = td.virtualTypeAtleastDefinition0) \vee$

$isSubtype0(td.virtualTypeInheritsDefinition0, td.virtualTypeAtleastDefinition0))$

If both **inherits** and **atleast** are used then the inherited type shall be identical to or be a subtype of the constraint.

```

 $\forall td, td1 \in \langle \text{block type definition} \rangle \cup \langle \text{process type definition} \rangle \cup \langle \text{procedure definition} \rangle \cup$ 
 $\langle \text{composite state type definition} \rangle:$ 
 $isRedefinedType0(td) \wedge (td1 = td.superCounterpart0) \Rightarrow$ 
  (
    let  $sp = td.specialization0$ 
    in
    let  $vc = take(\{vc \in \langle \text{virtuality constraint} \rangle: vc.surroundingScopeUnit0 = td1\})$ 
    in
     $(sp \neq \text{undefined}) \wedge (vc = \text{undefined}) \Rightarrow$ 
       $isSubtype0(td.virtualTypeInheritsDefinition0, td1.virtualTypeAtleastDefinition0)$ 
    endlet //  $vc$ 
    endlet //  $sp$ 
  )

```

In the case of an implicit constraint, redefinition involving **inherits** shall be a subtype of the constraint.

## Mapping to abstract syntax

The  $\langle \text{virtuality constraint} \rangle$  is always ignored in the mapping.

## Auxiliary functions

Determine if a  $\langle \text{block type definition} \rangle$ , a  $\langle \text{process type definition} \rangle$ , an  $\langle \text{internal procedure definition} \rangle$  or a  $\langle \text{composite state type definition} \rangle$  is a virtual type.

```

 $isVirtualType0(td: \langle \text{block type definition} \rangle \cup \langle \text{process type definition} \rangle \cup \langle \text{internal procedure definition} \rangle \cup$ 
 $\langle \text{composite state type definition} \rangle): \text{BOOLEAN} =_{\text{def}}$ 
 $td.virtuality0 \in \{\text{virtual}, \text{redefined}\}$ 

```

Determine if a  $\langle \text{block type definition} \rangle$ , a  $\langle \text{process type definition} \rangle$ , an  $\langle \text{internal procedure definition} \rangle$  or a  $\langle \text{composite state type definition} \rangle$  is a redefined type.

```

 $isRedefinedType0(td: \langle \text{block type definition} \rangle \cup \langle \text{process type definition} \rangle \cup \langle \text{internal procedure definition} \rangle$ 
 $\cup \langle \text{composite state type definition} \rangle): \text{BOOLEAN} =_{\text{def}}$ 
 $td.virtuality0 \in \{\text{redefined}, \text{finalized}\}$ 

```

Get the virtuality for a definition.

```

### F2.2.5.8.3 Virtual transitions/save

#### Conditions on concrete syntax

∀ *ad* ∈ <agent definition> ∪ <textual typebased agent definition> ∪ <composite state definition> ∪  
 <typebased composite state>:  
 ( (∀ *strt* ∈ <start>: *strt* ∈ *ad*.startSet0 ⇒ *strt*.virtuality0 = *undefined*) ∧  
 (∀ *s* ∈ <state>: (*s* ∈ *ad*.stateSet0) ⇒  
   (*s*.s-<input part>.virtuality0 = *undefined*) ∧

$(s.s\text{-}\langle\text{priority input}\rangle.\text{virtuality0} = \text{undefined}) \wedge$   
 $(s.s\text{-}\langle\text{save part}\rangle.\text{virtuality0} = \text{undefined}) \wedge$   
 $(s.s\text{-}\langle\text{spontaneous transition}\rangle.\text{virtuality0} = \text{undefined}) \wedge$   
 $(s.s\text{-}\langle\text{continuous signal}\rangle.\text{virtuality0} = \text{undefined})$   
 ) )

Virtual transitions or saves shall not appear in agent (set of instances) definitions, or in composite state definitions. See clause 8.4 *Concrete grammar* of [ITU-T Z.103].

$\forall s \in \langle\text{state}\rangle: |\{st \in \langle\text{spontaneous transition}\rangle: (st.\text{parentAS0} = s) \wedge (st.\text{virtuality0} \neq \text{undefined})\}| \leq 1$

A state shall not have more than one virtual spontaneous transition. See item(a) clause 8.4.3 *Concrete grammar* of [ITU-T Z.102].

$(\forall ip \in \langle\text{input part}\rangle:$   
 $(ip.\text{virtuality0} \neq \text{undefined}) \Rightarrow ip.s\text{-}\langle\text{input list}\rangle.s\text{-}\langle\text{asterisk input list}\rangle = \text{undefined}) \wedge$   
 $(\forall sp \in \langle\text{save part}\rangle:$   
 $(sp.\text{virtuality0} \neq \text{undefined}) \Rightarrow sp.s\text{-}\langle\text{save list}\rangle.s\text{-}\langle\text{asterisk save list}\rangle = \text{undefined})$

An input or save with  $\langle\text{virtuality}\rangle$  shall not contain  $\langle\text{asterisk}\rangle$ . See item(b) clause 8.4 *Concrete grammar* [ITU-T Z.103].

### Auxiliary functions

Get the set of  $\langle\text{start}\rangle$  items defined in a given definition.

```

startSet0(td: <agent definition> ∪ <textual typebased agent definition> ∪ <agent type definition> ∪

## F2.2.5.8.4 Virtual method

### Conditions on concrete syntax

```

∀ os ∈ <operation signature>:
    (os.entityKind0 = method) ∧ (os.virtuality0 ∈ {redefined, finalized}) ⇒
        ∃ os1 ∈ <operation signature>: (os1 = os.superCounterpart0) ∧
            isOperationSignatureCompatible0(os, os1) ∧
            (let fpl = os.operationSignatureParameterList0 in
                (let fpl1 = os1.operationSignatureParameterList0 in
                    ∀ i ∈ 1..fpl.length:
                        (fpl[i].s-<formal parameter>.s-<parameter kind> =
                            fpl1[i].s-<formal parameter>.s-<parameter kind>))
                )
            )
endlet
endlet

∀ od ∈ <operation definition>:
    (od.entityKind0 = method) ∧ (od.virtuality0 ∈ {redefined, finalized}) ⇒
        ∃ od1 ∈ <operation definition>:
            ( od1 = od.superCounterpart0) ∧
            ( od1.s-<operation heading>.s-<operation result>.s-<result aggregation> =
                od.s-<operation heading>.s-<operation result>.s-<result aggregation>))

```

When a method is redefined in a specialization, its signature shall be sort compatible with the corresponding signature in the base type, and further, if the *Result* in the *Operation-signature* denotes a sort A, then the *Result* of the redefined method shall only denote a sort B such that B is sort compatible to A. A redefinition of a virtual method shall not change the <parameter kind> in any <argument> of the inherited <operation signature>. A redefinition of a virtual method shall not change the <aggregation kind> of the <operation result> of the inherited <operation definition>. See clause 12.1.3 *Concrete grammar* of [ITU-T Z.107].

### Auxiliary functions

Determine if two <operation signature>s are compatible.

```

isOperationSignatureCompatible0(os: <operation signature>, os1: <operation signature>): BOOLEAN =def
isSortCompatible0(os.s-<result>.s-<sort>, os1.s-<result>.s-<sort>) ∧
( let fpl = os.operationSignatureParameterList0 in
    let fpl1 = os1.operationSignatureParameterList0 in
        (fpl.length = fpl1.length) ∧
        (∀ i ∈ 1..fpl.length:
            (isSortCompatible0(fpl[i].s-<sort>, fpl1[i].s-<sort>)))
        )
endlet // fpl1

```

```

    endlet // fpl
)

```

## F2.2.6 Agents

### Abstract syntax

<i>Agent-definition</i>	::	<i>Agent-name</i> <i>Number-of-instances</i> <i>Agent-type-identifier</i>
<i>Number-of-instances</i>	::	<i>Initial-number</i> [ <i>Maximum-number</i> ] <i>Lower-bound</i>
<i>Initial-number</i>	=	<i>NAT</i>
<i>Maximum-number</i>	=	<i>NAT</i>
<i>Lower-bound</i>	=	<i>NAT</i>
<i>Agent-formal-parameter</i>	=	<i>Parameter</i>
<i>Parameter</i>	::	<i>Variable-name</i> <i>Sort-reference-identifier</i> <i>Parameter-aggregation</i>
<i>Parameter-aggregation</i>	::	<i>Aggregation-kind</i>
<i>State-machine</i>	::	<i>State-name</i> <i>Nextstate-parameters</i> <i>Composite-state-type-identifier</i>
<i>State-transition-graph</i>	::	[ <i>State-start-node</i> ] <i>Named-start-node-set</i> <i>State-node-set</i> <i>Free-action-set</i>

### Conditions on abstract syntax

$\forall d \in \text{Agent-definition}: d.\text{agentKind1} = \text{SYSTEM} \Rightarrow d.\text{parentAS1} \notin \text{Agent-type-definition}$

An Agent with the Agent-kind **SYSTEM** shall not be contained in any other Agent. See clause 9.1 Abstract grammar of [ITU-T Z.101].

$\forall d \in \text{Agent-definition}: d.\text{agentKind1} = \text{system} \Rightarrow$   
 $(d.\text{s-Number-of-instances.s-Initial-number} = 1 \wedge d.\text{s-Number-of-instances.s-Maximum-number} = 1)$

In an Agent with the Agent-kind **SYSTEM** the Initial-number of instances is 1 and the Maximum-number of instances is 1. See clause 9.1 Abstract grammar of [ITU-T Z.101].

$\forall ni \in \text{Number-of-instances}:$   
 $((ni.\text{s-Maximum-number} \neq \text{undefined} \Rightarrow ni.\text{s-Initial-number} \leq ni.\text{s-Maximum-number})$   
 $\wedge (ni.\text{s-Lower-bound} \leq ni.\text{s-Initial-number}))$

If there is a Maximum-number, the Initial-number of instances shall be less than or equal to Maximum-number and Maximum-number shall be greater than zero. The Lower-bound shall be less than or equal to the Initial-number. See clause 9 Abstract grammar of [ITU-T Z.101].

### Concrete syntax

```

<agent definition> =
    <system definition>
    | <block definition>
    | <process definition>
<agent structure> ::
    <entity in agent>*
    { <interaction> | <agent body> }

```

```

<interaction> ::
  { <channel to channel connection>
  | <channel definition>
  | <agent definition>
  | <block reference>
  | <process reference>
  | <textual typebased agent definition> }*
  [<state machine>]

<state machine> =
  <typebased composite state>
  | <composite state list item>

<agent instantiation> ::
  [<number of instances>]<agent additional heading>

<agent additional heading> ::
  [<specialization>] [<agent formal parameters>]

<entity in agent> =
  <block type definition>
  | <block type reference>
  | <composite state definition>
  | <composite state type definition>
  | <composite state type reference>
  | <data definition>
  | <gate in definition>
  | <procedure definition>
  | <procedure reference>
  | <process type definition>
  | <process type reference>
  | <remote procedure definition>
  | <remote variable definition>
  | <select definition>
  | <signal definition list>
  | <signal list definition>
  | <timer definition>
  | <valid input signal set>
  | <variable definition>

<valid input signal set> :: [ <signal list> ]

<number of instances> ::
  [<initial number>] [<maximum number>] [ <lower bound> ]

<initial number> = <Natural><simple expression>
<maximum number> = <Natural><simple expression>
<lower bound> = <Natural><simple expression>

<agent formal parameters> :: { <aggregation kind> <parameters of sort> }*
<parameters of sort> :: <variable><name>+ <sort>

<agent body> ::
  [<start>] {<state> | <free action>}*

```

NOTE 1 – In [ITU-T Z.106] <entity in agent> includes <imported procedure specification>/<imported variable specification>, but these have no SDL-2010 meaning (see clause 9 of [ITU-T Z.103]), and <macro definition> is removed by step 1 transformations, therefore none of these three items appears in AS0 <entity in agent>.

### Conditions on concrete syntax

$\forall ainst \in \langle \text{agent instantiation} \rangle$ :  
 $ainst.s-\langle \text{agent additional heading} \rangle.s-\langle \text{agent formal parameters} \rangle \neq \text{undefined} \Rightarrow$   
 $ainst.s-\langle \text{number of instances} \rangle \neq \text{undefined}$

In <agent instantiation>, if <agent formal parameters> are present, <number of instances> shall be present, even if both <initial number> and <maximum number> are omitted. See clause 9 *Concrete grammar* of [ITU-T Z.103].

$\forall afps \in \langle \text{agent formal parameters} \rangle$ :  
 $afps.parentAS0 \in (\langle \text{composite state type heading} \rangle \cup \langle \text{state aggregation type heading} \rangle \cup \langle \text{agent additional heading} \rangle \cup \langle \text{composite state heading} \rangle) \Rightarrow afps.length > 0$

When used in the concrete syntax (occurs in places in the condition above), the <agent formal parameters> list shall have at least one item. However, it is defined with "\*" rather than "+" so that it can be used as an empty list within conditions, transformations, mappings and functions.

## Transformations

```
< <system definition>(uses, <system heading>(n, addHead), body) >
=12=>
let nn=newName in
< mk-<textual typebased system definition>(
  mk-<typebased system heading>(n, mk-<type expression>( mk-<identifier>(undefined, nn), empty)),
  mk-<system type definition>(uses,
    mk-<system type heading>(empty, nn,
      mk-<agent type additional heading>(empty, undefined, addHead)),
    body) >
endlet // nn
```

```
< <block definition>(uses, <block heading>(*, n, <agent instantiation>(inst, addHead)), body) >
=12=> // * is optional qualifier which is ignored
let nn=newName in
< mk-<textual typebased block definition>(
  mk-<typebased block heading>(n, inst, mk-<type expression>( mk-<identifier>(undefined, nn),
    empty))),
  mk-<block type definition>(uses,
    mk-<block type heading>(empty, undefined, nn,
      mk-<agent type additional heading>(empty, undefined, addHead)),
    body) >
endlet // nn
```

```
< <process definition>(uses, <process heading>(*, n, <agent instantiation>(inst, addHead)), body) >
=12=> // * is optional qualifier which is ignored
let nn=newName in
< mk-<textual typebased process definition>(
  mk-<typebased process heading>(n, inst, mk-<type expression>( mk-<identifier>(undefined, nn),
    empty))),
  mk-<process type definition>(uses,
    mk-<process type heading>(empty, undefined, nn,
      mk-<agent type additional heading>(empty, undefined, addHead)),
    body) >
endlet // nn
```

An agent definition has an implied anonymous agent type defined by the content of the definition and used for the agent set. See the introduction of clause 9 of [ITU-T Z.103].

NOTE 2 – In clause F2.2.5.1.1 an <agent structure> with an <agent body> transformed into an <agent structure> with an <interaction>.

```
<agent formal parameters>(params)
provided  $\exists i \in 1..params.length: params[i].s-\langle \text{parameters of sort} \rangle.s-\langle \text{name} \rangle-\mathbf{seq}.length \neq 1$ 
=5=>
mk-<agent formal parameters>(
  < if  $params[i].s-\langle \text{parameters of sort} \rangle.s-\langle \text{name} \rangle-\mathbf{seq}.length \neq 1$ 
  then // replacement list elements – two (aggregation kind, parameters of sort) pairs
    (  $params[i].s-\langle \text{aggregation kind} \rangle,$  //
```

```

    mk-< parameters of sort > (
      < params[i].s-<parameters of sort>.s-<name>-seq.head >,
      params[i].s-<parameters of sort>.s-<sort>)
  ), // first (aggregation kind, parameters of sort) pair
  ( params[i].s-<aggregation kind>,
    mk-< parameters of sort > (
      params[i].s-<parameters of sort>.s-<name>-seq.tail, // transform again if >1 name in tail
      params[i].s-<parameters of sort>.s-<sort>)
    ) // second (aggregation kind, parameters of sort) pair
  else params[i] // only one name, no change needed
endif
: i ∈ 1..params.length
> // list of (aggregation kind, parameters of sort) pairs
)

```

An <agent formal parameters> list item with a <parameters of sort> that defines multiple parameter names is replaced by a sequence of <agent formal parameters> list items with the same <aggregation kind> each <parameters of sort> defining one name. See clause 8.1.1.1 *Model* of [ITU-T Z.101].

*The following transformation is covered by the transformation for agent types.*

An agent with an <agent body> or an <agent body area> is shorthand for an agent having only a state machine, but no contained agents. This state machine is obtained by replacing the <agent body> or <agent body area> by a composite state definition. This composite state definition has the same name as the agent and its State-transition-graph is represented by the <agent body> or the <agent body area>.

*The following transformation is covered by the dynamic semantics.*

In all agent instances, four anonymous variables of the pid sort of the agent (for agents not based on an agent type) or the pid sort of the agent type (for type based agents) are declared and are, in the following, referred to by self, parent, offspring and sender. They give a result for:

- a) the agent instance (self);
- b) the creating agent instance (parent);
- c) the most recent agent instance created by the agent instance (offspring);
- d) the agent instance from which the last input signal has been consumed (sender) (see also clause 11.3 of [ITU-T Z.101]).

These anonymous variables are accessed using pid expressions as further explained in clause 12.3.4.2 of [ITU-T Z.101].

For all agent instances present at system initialization, parent is initialized to Null.

For all newly created agent instances, sender and offspring are initialized to Null.

## Mapping to abstract syntax

```

| <number of instances>(init, max, lower) then
  mk-Number-of-instances(
    if init ≠ undefined then Mapping(init) else 1 endif,
    if max ≠ undefined then Mapping(max) else undefined endif,
    if lower ≠ undefined then Mapping(lower) else 0 endif)

```

If <initial number> is omitted, then *Initial-number* is 1. If <maximum number> is omitted, then *Maximum-number* is unbounded (it is omitted in *Number-of-instances*). If the <lower bound> is omitted, the *Lower-bound* is zero. See clause 9 *Concrete grammar* of [ITU-T Z.101].

```

| <agent formal parameters>(param) then < Mapping(param[i]) : i ∈ 1..param.length >

```

```

| param=<parameters of sort>( < name >, s) then

```

```

mk-Parameter(Mapping(name), // Variable-name
Mapping(s), // Sort-reference-identifier
mk-Parameter-aggregation(
  case parent=param.parentAS0 of // Parameter aggregation
  | <agent formal parameters> then Mapping(parent.s-<aggregation kind>)
  | <formal variable parameters> then Mapping(parent.s-<parameter aggregation>)
  endcase // param
) )

```

### F2.2.6.1 System

#### Concrete syntax

```

<system definition> ::
  <package use clause>* <system heading> <agent structure>
<system heading> :: <system<name> <agent additional heading>

```

#### Conditions on concrete syntax

$\forall sd \in \langle \text{system heading} \rangle: sd.agentLocalFormalParameterList0 = \text{empty}$

The <agent additional heading> in a <system definition> shall not include <agent formal parameters>. See clause 9.1 *Concrete grammar* of [ITU-T Z.103].

### F2.2.6.2 Block

#### Concrete syntax

```

<block definition> ::
  <package use clause>* <block heading> <agent structure>
<block heading> ::
  <qualifier> <block<name> <agent instantiation>

```

### F2.2.6.3 Process

#### Concrete syntax

```

<process definition> ::
  <package use clause>* <process heading> <agent structure>
<process heading> :: <qualifier> <process<name> <agent instantiation>

```

### F2.2.6.4 Procedure

#### Abstract syntax

```

Procedure-definition           ::   Procedure-name
                                   Procedure-formal-parameter*
                                   [ Result ]
                                   [ Procedure-identifier ]
                                   Data-type-definition-set
                                   Syntype-definition-set
                                   Variable-definition-set
                                   Composite-state-type-definition-set
                                   Procedure-definition-set
                                   Procedure-graph
                                   [ Abstract ]

Procedure-formal-parameter     =   In-parameter
                                   |   Inout-parameter
                                   |   Out-parameter

In-parameter                   ::   Parameter

Inout-parameter                ::   Parameter

Out-parameter                  ::   Parameter

```

<i>Procedure-graph</i>	::	[ <i>Procedure-start-node</i> ] <i>State-node-set</i> <i>Free-action-set</i>
<i>Result</i>	::	<i>Sort-reference-identifier</i> <i>Result-aggregation</i>
<i>Result-aggregation</i>	::	<i>Aggregation-kind</i>

## Concrete syntax

<procedure definition> =  
     <external procedure definition>  
     | <internal procedure definition>

<internal procedure definition> ::  
     <package use clause>\* <procedure heading> <entity in procedure>\*  
     { <procedure body> | [ <virtuality> ] <statements> }

<procedure preamble> :: <type preamble> [<exported>]

<exported> :: [ <remote procedure identifier> ]

<procedure heading> ::  
     <procedure preamble> <qualifier> <procedure name>  
     [ <formal context parameters> ]  
     [ <virtuality constraint> ]  
     [ <specialization> ]  
     <procedure formal parameters>  
     [ <procedure result> ]

<procedure formal parameters> =  
     <formal variable parameters>\*

<entity in procedure> =  
     <variable definition>  
     | <data definition>

     | <composite state type reference>  
     | <select definition>

<procedure body> ::  
     [ <start> ] { <state> | <free action> }\*

<external procedure definition> :: <procedure name> <procedure signature>

<formal variable parameters> :: <parameter kind> <parameter aggregation> <parameters of sort>

<parameter aggregation> :: <aggregation kind>

<parameter kind> = [ **inout** | **in** | **out** ]

<procedure result> :: <result aggregation> [ <variable name> ] <sort>

<result aggregation> :: <aggregation kind>

<procedure signature> :: <formal parameter>\* [ <result> ]

## Conditions on concrete syntax

$\forall pd \in \langle \text{procedure definition} \rangle : pd.isExported0 \Rightarrow$   
 $pd.formalContextParameterList0 = \text{empty} \wedge$   
 $pd.surroundingScopeUnit0 \in$   
 $\langle \text{agent type definition} \rangle \cup \langle \text{composite state type definition} \rangle \cup$   
 $\langle \text{agent definition} \rangle \cup \langle \text{composite state definition} \rangle$

An exported procedure shall not have formal context parameters and its enclosing scope shall be an agent type or a composite state type. See clause 9.4 *Concrete grammar* of [ITU-T Z.102].

NOTE 1 – Although the condition requires the enclosing scope to be an agent type or composite state type, the alternatives for agent and composite state are included, so that these are valid before they are transformed to an agent type or composite state type that surrounds the exported procedure.

$$\forall vd \in \langle \text{variable definition} \rangle: \\ vd.surroundingScopeUnit0 \in \langle \text{procedure definition} \rangle \Rightarrow \neg vd.isExported0$$

$\langle \text{variable definition} \rangle$  in an  $\langle \text{internal procedure definition} \rangle$ , cannot contain **exported**  $\langle \text{variable name} \rangle$ s

$$\forall pd1, pd2 \in \langle \text{internal procedure definition} \rangle: \\ (parentAS0ofKind(pd1, \langle \text{agent type definition} \rangle) = \\ parentAS0ofKind(pd2, \langle \text{agent type definition} \rangle) \wedge \\ pd1.isExported0 \wedge pd2.isExported0 \wedge pd1 \neq pd2) \Rightarrow \\ (pd1.s-\langle \text{procedure heading} \rangle.s-\langle \text{procedure preamble} \rangle.s-\langle \text{exported} \rangle.s-\langle \text{identifier} \rangle \neq \\ pd1.s-\langle \text{procedure heading} \rangle.s-\langle \text{procedure preamble} \rangle.s-\langle \text{exported} \rangle.s-\langle \text{identifier} \rangle)$$

Two exported procedures in an agent type or any enclosed composite state type of the agent type shall not mention the same  $\langle \text{remote procedure identifier} \rangle$ . See clause 9.4 *Concrete grammar* of [ITU-T Z.102].

NOTE 2 – The *parentAS0ofKind* search does not need to include enclosed composite state types, because the agent type is a parent of these also. An agent definition that contains an exported procedure definition is transformed to a typebased agent that instantiates an agent type definition, so the check on the agent type definition is sufficient.

$$\forall te \in \langle \text{type expression} \rangle: te.baseType0 \notin \langle \text{external procedure definition} \rangle \wedge \\ \forall procCons \in \langle \text{procedure constraint} \rangle: procCons.s-\langle \text{identifier} \rangle \neq \text{undefined} \Rightarrow \\ getEntityDefinition0(procCons.s-\langle \text{identifier} \rangle, \mathbf{procedure}) \notin \\ \langle \text{external procedure definition} \rangle$$

An external procedure cannot be mentioned in a  $\langle \text{type expression} \rangle$  or in a  $\langle \text{procedure constraint} \rangle$ .

## Transformations

$$\langle \text{formal variable parameters} \rangle(\text{undefined}, \text{aggr}, \text{params}) \\ =5 \Rightarrow \\ \mathbf{mk}-\langle \text{formal variable parameters} \rangle(\mathbf{in}, \text{aggr}, \text{params})$$

A formal parameter with no explicit  $\langle \text{parameter kind} \rangle$  has the implicit  $\langle \text{parameter kind} \rangle$  **in**. See clause 9.5 *Model* of [ITU-T Z.103].

$$fvp = \langle \text{formal variable parameters} \rangle(\text{kind}, \text{ak}, \text{params}) \\ \mathbf{provided} \\ \text{params.s-}\langle \text{name} \rangle\text{-seq.length} \neq 1 \\ =5 \Rightarrow \\ \mathbf{mk}-\langle \text{formal variable parameters} \rangle(\text{kind}, \text{ak}, \langle \text{params.s-}\langle \text{name} \rangle\text{-seq.head} \rangle)$$

$$\mathbf{mk}-\langle \text{formal variable parameters} \rangle(\text{kind}, \text{ak}, \text{params.s-}\langle \text{name} \rangle\text{-seq.tail}) // \text{transform again if } >1 \text{ name in tail}$$

A  $\langle \text{formal variable parameters} \rangle$  with a  $\langle \text{parameters of sort} \rangle$  that defines multiple parameter names is replaced by a sequence of  $\langle \text{formal variable parameters} \rangle$  with the same  $\langle \text{parameter kind} \rangle$  and  $\langle \text{aggregation kind} \rangle$ , and each  $\langle \text{parameters of sort} \rangle$  defining one name. See clause 9.4 *Model* of [ITU-T Z.101].

$$ph = \langle \text{procedure heading} \rangle(\text{pre}, \text{q}, \text{n}, \text{fcp}, \text{vc}, \text{sp}, \text{fpars}, \text{res}) \\ \mathbf{provided} \text{ expandFormalVarParams0(fpars).length} > \text{fpars.length} \\ =5 \Rightarrow \\ \mathbf{mk}-\langle \text{procedure heading} \rangle(\text{pre}, \text{q}, \text{n}, \text{fcp}, \text{vc}, \text{sp}, \text{expandFormalVarParams0(fpars)}, \text{res})$$

If any <parameters of sort> in a formal parameter list defines more than one name, the formal parameter list is expanded so that each <parameters of sort> defines only one name. Derived from clause 8.1.1.1 *Concrete grammar* of [ITU-T Z.101].

```

rbody =<return body>(undefined)
provided
  surroundingScopeUnit0(rbody) ∈ <internal procedure definition>
  ∧ surroundingScopeUnit0(rbody).s-<procedure heading>.s-<procedure result>.s-<name> ≠ undefined
=8=>
mk-<return body>( mk-<expression>( mk-<operand5>( mk-<variable access>(
  mk-<identifier>( surroundingScopeUnit0(rbody).fullQualifierWithin0, // var qual - defined in procedure
    surroundingScopeUnit0(rbody).s-<procedure heading>.s-<procedure result>.s-<name> // var name
  ) // identifier
  ))) // return body, expression, operand5, variable access

```

When a <variable name> is present in <procedure result>, each <return body> within the procedure graph without an <expression> is replaced by a <return body> containing the <variable name> as the <expression>.

```

p=<internal procedure definition>(uses,
  h=<procedure heading>(*, *, *, *, *, *, *, <procedure result>(resAgKind, resName, resSort), *),
  entities, body)
provided resName ≠ undefined ∧ resName ∉ {n in v.s-<name>-seq | v ∈ <variables of sort>:
  v.parentAS0.parentAS0.parentAS0 = p }
=8=>
mk-<internal procedure definition>
  ( uses, h,
    entities ^ mk-<variable definition>
      ( undefined,
        < mk-<variables of sort>
          (resAgKind, < resName >, resSort, undefined)
        >
      ),
    body)

```

A <procedure result> with <variable name> is derived syntax for a <variable definition> with <variable name> and <sort> in <variables of sort>. If there is a <variable definition> involving <variable name> no further <variable definition> is added.

*The following statement is covered by the dynamic semantics.*

A <procedure start area> which contains <virtuality> of virtual or redefined, a <start> of a <procedure body> which contains <virtuality> of virtual or redefined, or a <statements> in an <internal procedure definition> following <virtuality> of **virtual** or **redefined** is called a virtual procedure start. Virtual procedure start is further described in clause 8.4.3 of [ITU-T Z.102].

```

< <external procedure definition>(*, *) > =7=> empty

```

An external procedure definition is not considered in the dynamic semantics.

## Mapping to abstract syntax

```

| <internal procedure definition>(*, <procedure heading>(*, *, *, *, *, parent, pars, result, *), entities, body) then
let entitiesSet = { Mapping(entities[i]: i ∈ 1..entities.length) in
mk-Procedure-definition(Mapping(n),
  < Mapping(pars[j]): j ∈ 1..pars.length >,
  Mapping(result),
  Mapping(parent),
  { e ∈ entitiesSet: e ∈ Data-type-definition }
  ∪ { choiceForInterfaceI(if): (if in entities ∧ if ∈ <interface definition> ) } // choices for Interface-defs,
  { e ∈ entitiesSet: e ∈ Syntype-definition },

```

```

    { e ∈ entitiesSet: e ∈ Variable-definition },
    { e ∈ entitiesSet: e ∈ Composite-state-type-definition },
    { e ∈ entitiesSet: e ∈ Procedure-definition },
    Mapping(body) )
endlet // entitiesSet

| <formal variable parameters>(in, paggr, param) then mk-In-parameter(Mapping(param))

| <formal variable parameters>(out, paggr, param) then mk-Out-parameter(Mapping(param))

| <formal variable parameters>(inout, paggr, param) then mk-Inout-parameter(Mapping(param))

| <procedure result>( rak, *, rsort) then mk-Result(Mapping(rsort),mk-Result-aggregation(Mapping(rak)))

```

NOTE 3 – If a variable name is given in <procedure result>, there is a model transform (see above) to ensure the variable is defined, and the name is ignored in the mapping.

```

| <procedure body>(start, nodes) then
let nodeSet = { Mapping(nodes[i]:i ∈ 1..nodes.length} in
mk-Procedure-graph(
    Mapping(start),
    { sn ∈ nodeSet: sn ∈ State-node } // State-node-set
    { fa ∈ nodeSet: fa ∈ Free-action } // Free-action-set
)
endlet // nodeSet

```

## Auxiliary functions

Determine if a <variable definition> or an <internal procedure definition> is exported.

```

isExported0(vp: <variable definition> ∪ <internal procedure definition>): BOOLEAN =def
case vp of
| <variable definition>(vlist) then
    if vlist.head ∈ <exported variables of sort> then true else false endif
| <internal procedure definition> then
    if vp.s-<procedure heading>.s-<procedure preamble>.s-<exported> = undefined
    then false
    else true
    endif
otherwise false
endcase

```

Get the formal parameter list for an <internal procedure definition>.

```

procedureFormalParameterList0(pd: <internal procedure definition>): <name>* =def
    pd.localProcedureFormalParameterList0 ^ pd.inheritedProcedureFormalParameterList0

```

```

localProcedureFormalParameterList0(pd: <internal procedure definition>): <name>* =def
let fpl=pd.s-<procedure heading>.s-<formal variable parameters>-seq in
    if fpl = empty then empty
    else
        <f.s-<parameters of sort>.s-<variable<name>-seq | f in fpl >
    endif
endlet

```

```

inheritedProcedureFormalParameterList0(pd: <internal procedure definition>): <name>* =def
let sp = pd.specialization0 in
    if sp = undefined then empty
    else sp.s-<type expression>.baseType0.procedureFormalParameterList0
endlet

```

Get the formal parameter list for a <procedure signature>.

*procedureSignatureParameterList0*(*ps*: <procedure signature>):<formal parameter>\* =<sub>def</sub>  
*ps.s*-<formal parameter>-**seq**

Determine if a *Procedure-definition* is functional: that is, it does not contain a state, no in/out or out parameters, no assignment to variables defined outside the procedure and every contained value returning procedure call or call node calls a functional procedure.

*isFunctionall*(*pd*: *Procedure-definition*): *BOOLEAN* =<sub>def</sub>  
 $(\neg \exists st \in \text{State-node}: \text{isAncestorASI}(pd, st))$  // no local states  
 $\wedge (\forall param \in pd.s\text{-implicit-seq} : param \in \text{In-parameter})$  // only in parameters  
 $\wedge (\forall ass \in \text{Assignment} : \text{isAncestorASI}(pd, ass) \Rightarrow \text{isAncestorASI}(pd, \text{getEntityDefinition1}(ass.s\text{-Variable-identifier}, \text{variable})))$  // var defined in proc  
 $\wedge (\forall vpc \in \text{Value-returning-call-node} : \text{isAncestorASI}(pd, vpc) \Rightarrow \text{isFunctionall}(\text{getEntityDefinition1}(vpc.s\text{-Procedure-identifier}, \text{procedure})))$  // functional  
 $\wedge (\forall pc \in \text{Call-node} : \text{isAncestorASI}(pd, pc) \Rightarrow \text{isFunctionall}(\text{getEntityDefinition1}(pc, \text{procedure})))$  // functional

Get the formal parameter list for an *Agent-type-definition*, a *Composite-state-type-definition*, or a *Procedure-definition*.

*formalParameterList1*  
(*d*: *Agent-type-definition*  $\cup$  *Composite-state-type-definition*  $\cup$  *Procedure-definition*):  
*Parameter*\* =<sub>def</sub>  
*d.localFormalParameterList1*  $\hat{}$  *d.inheritedFormalParameterList1*

*localFormalParameterList1*  
(*d*: *Agent-type-definition*  $\cup$  *Composite-state-type-definition*  $\cup$  *Procedure-definition*):  
*Parameter*\* =<sub>def</sub>  
**case** *d* **of**  
| *Agent-type-definition* **then** *d.s-Agent-formal-parameter-seq*  
| *Composite-state-type-definition* **then** *d.s-Composite-state-formal-parameter-seq*  
| *Procedure-definition* **then** *d.s-Procedure-formal-parameter-seq*  
**otherwise empty endif**  
**endcase**

*inheritedFormalParameterList1*(*d*: *Agent-type-definition*  $\cup$  *Composite-state-type-definition*  $\cup$   
*Procedure-definition*): *Parameter*\* =<sub>def</sub>  
**let** *d1* = *take*({*d1*  $\in$  *Agent-type-definition*  $\cup$  *Composite-state-type-definition*  $\cup$  *Procedure-definition*:  
*isDirectSuperType1*(*d1*, *d*)} **in**  
**if** *d1*  $\neq$  *undefined* **then** *d1.formalParameterList1*  
**else empty endif**  
**endlet**

Determine if the sort list of *Expression* items corresponds by position to the *Sort-reference-identifier* list.

*isActualAndFormalParameterMatched1*  
(*expl*: [*Expression*]\*, *fpsl*: *Sort-reference-identifier*\*): *BOOLEAN* =<sub>def</sub>  
 $(expl.length = fpsl.length) \wedge$   
 $(\forall i \in 1..expl.length: expl[i] = \text{undefined} \vee \text{CompatibleTo1}(expl[i].staticSort1, fpsl[i]))$

Get the sort list of the formal parameters of the given definition.

*formalParameterSortList1*  
(*d*: *Agent-type-definition*  $\cup$  *Composite-state-type-definition*  $\cup$  *Procedure-definition*  $\cup$   
*Operation-signature*): *Sort-reference-identifier*\* =<sub>def</sub>  
**case** *d* **of**  
| *Agent-type-definition*  $\cup$  *Composite-state-type-definition*  $\cup$  *Procedure-definition* **then**  
<*param.s-Sort-reference-identifier* | *param* **in** *d.formalParameterList1*>  
| *Operation-signature* **then** <*fa.s-Argument* | *fa* **in** *d.s-Formal-argument-seq*>  
| *Signal-definition*  $\cup$  *Timer-definition* **then** *d.s-Sort-reference-identifier-seq*  
**endcase**

Get the set of state nodes included in a type definition, state node or a state partition.

```
stateNodeSet1(d: TYPEDEFINITION1 ∪ State-node ∪ State-partition): State-node-set =def
  case d of
  | TYPEDEFINITION1 then d.localStateNodeSet1 ∪ d.inheritedStateNodeSet1
  | State-node then
    if d.s-Composite-state-type-identifier ≠ undefined then d.baseType1.stateNodeSet1 ∪ {d}
    else {d}
  | State-partition then d.baseType1.stateNodeSet1
  otherwise ∅
endcase
```

Get the set of state nodes defined locally in a type definition.

```
localStateNodeSet1(d: TYPEDEFINITION1): State-node-set =def
  case d of
  | Agent-type-definition then
    if d.State-machine ≠ undefined then
      d.State-machine.baseType1.stateNodeSet1
    else ∅
  | Procedure-definition then
    {sn.stateNodeSet1: sn ∈ d.s-Procedure-graph.s-State-node-set}
  | Composite-state-type-definition then
    if d.s-implicit ∈ Composite-state-graph then
      {sn.stateNodeSet1: sn ∈ d.s-implicit.s-State-transition-graph.s-State-node-set}
    else // d.s-implicit ∈ State-aggregation-node
      {sp.stateNodeSet1: sp ∈ d.s-implicit.s-State-partition-seq.toSet}
  otherwise ∅
endcase
```

Get the set of state nodes defined in a super type.

```
inheritedStateNodeSet1(d: TYPEDEFINITION1): State-node-set =def
  case d of
  | Agent-type-definition then
    if d.s-Agent-type-identifier ≠ undefined then
      getEntityDefinition1(d.s-Agent-type-identifier, agent type).stateNodeSet1
    else ∅
  | Procedure-definition then
    if d.s-Procedure-identifier ≠ undefined then
      getEntityDefinition1(d.s-Procedure-identifier, procedure).stateNodeSet1
    else ∅
  | Composite-state-type-definition then
    if d.s-Composite-state-type-identifier ≠ undefined then
      getEntityDefinition1(d.s-Composite-state-type-identifier, state type).stateNodeSet1
    else ∅
  otherwise ∅
endcase
```

The function *expandFormalVarParams0* expands an <formal variable parameters> list so that each <parameters of sort> contains only one <name>.

```
expandFormalVarParams0(fvps: <formal variable parameters>*): <formal variable parameters>* =def
  if fvps = empty then empty
  else
    if fvps.head.s-<parameters of sort>.s-<name>-seq.length = 1
    then fvps.head
    else <fvps.head.s-<parameter kind>, fvps.head.s-<parameter aggregation>,
      mk-<parameters of sort>( <fvps.head.s-<parameters of sort>.s-<name>-seq.head >,
        fvps.head.s-<parameters of sort>.s-<sort> ) > ^
      expandAgentFormalParams0(<fvps.head.s-<parameter kind>,
        fvps.head.s-<parameter aggregation>,
```

```

    mk-<parameters of sort>( <fvps.head.s-<parameters of sort>.s-<name>-seq.tail>,
      fvps.head.s-<parameters of sort>.s-<sort>
    ) >)
  endif
  if fvps.length =1 then empty
  else expandAgentFormalParams0(fvps.tail)
  endif
endif

```

## F2.2.7 Communication

### F2.2.7.1 Channel definition

#### Abstract syntax

<i>Channel-definition</i>	::	<i>Channel-name</i> [ <i>Encoding-rules</i> ] [ <b>NODELAY</b> ] <i>Channel-path-set</i>
<i>Channel-path</i>	::	<i>Channel-endpoint</i> <i>Originating-gate</i> <i>Channel-endpoint</i> <i>Destination-gate</i> <i>Signal-identifier-set</i>
<i>Originating-gate</i>	=	<i>Gate-identifier</i>
<i>Destination-gate</i>	=	<i>Gate-identifier</i>
<i>Channel-endpoint</i>	::	<i>Agent-identifier</i>   <i>State-identifier</i>   <b>ENV</b>

#### Conditions on abstract syntax

See clause 10.1 *Abstract grammar* of [ITU-T Z.101] except the condition on *Encoding-rules*.

$$\forall c \in \text{Channel-definition}: |c.s\text{-Channel-path-set}| \in \{1, 2\}$$

The *Channel-path-set* contains at least one *Channel-path* and no more than two.

$$\forall c \in \text{Channel-definition}: |c.s\text{-Channel-path}| = 2 \Rightarrow$$

$$(\forall p1, p2 \in c.s\text{-Channel-path}: p1 \neq p2 \Rightarrow$$

$$p1.s\text{-Originating-gate} = p2.s\text{-Destination-gate} \wedge p2.s\text{-Originating-gate} = p1.s\text{-Destination-gate})$$

When there are two paths, the channel is bidirectional and the *Originating-gate* of each *Channel-path* shall be the same as the *Destination-gate* of the other *Channel-path*.

$$\forall c \in \text{Channel-definition}: \forall p \in \text{Channel-path}: \forall d \in \text{Agent-type-definition}: \\ (p.s1\text{-Channel-endpoint} = p.s2\text{-Channel-endpoint}) \wedge \parallel \text{same agent}$$

$$\forall g1, g2 \in \text{Gate-definition}: (p.parentASI = c) \wedge (g1.parentASI = d) \wedge (g2.parentASI = d) \wedge (g1 \neq g2) \wedge \\ (p.s\text{-Originating-gate} = g1.identifier1) \wedge (p.s\text{-Destination-gate} = g2.identifier1) \Rightarrow \\ |c.s\text{-Channel-path-set}| = 1$$

If the *Originating-gate* and the *Destination-gate* are gates of the same agent, the channel shall be unidirectional (there shall be only one element in the *Channel-path-set*).

$$\forall c \in \text{Channel-definition}: \forall p \in \text{Channel-path}: \forall d \in \text{Composite-state-type-definition}: \\ (p.s1\text{-Channel-endpoint} = p.s2\text{-Channel-endpoint}) \wedge \parallel \text{same state machine}$$

$$\forall g1, g2 \in \text{Gate-definition}: (p.parentASI = c) \wedge (g1.parentASI = d) \wedge (g2.parentASI = d) \wedge (g1 \neq g2) \wedge \\ (p.s\text{-Originating-gate} = g1.identifier1) \wedge (p.s\text{-Destination-gate} = g2.identifier1) \Rightarrow \\ |c.s\text{-Channel-path-set}| = 1$$

If the *Originating-gate* and the *Destination-gate* are both gates of the same state machine, the channel shall be unidirectional (there shall be only one element in the *Channel-path-set*).

$$\forall c \in \text{Channel-definition}: \forall p \in \text{Channel-path}: \exists g1, g2 \in \text{Gate-definition}:$$

$$\begin{aligned}
& (p.\text{parentAS1} = c) \wedge \\
& ( ((p.\text{s-Originating-gate} = g1.\text{identifier1}) \wedge \\
& \quad (g1.\text{parentAS1} = c.\text{parentAS1} \vee g1.\text{parentAS1}.\text{parentAS1} = c.\text{parentAS1})) \wedge \\
& \quad ((p.\text{s-Destination-gate} = g2.\text{identifier1}) \wedge \\
& \quad \quad (g2.\text{parentAS1} = c.\text{parentAS1} \vee g2.\text{parentAS1}.\text{parentAS1} = c.\text{parentAS1})) \\
& )
\end{aligned}$$

The *Originating-gate* and *Destination-gate* shall be defined in the same scope unit (which includes directly enclosed scopes) in the abstract syntax in which the channel is defined.

$$\begin{aligned}
\forall c \in \text{Channel-definition}: \forall p \in c.\text{s-Channel-path-set}: \\
\text{getEntityDefinition1}(p.\text{s-Originating-gate}, \mathbf{gate}).\text{s-Encoding-rules} = c.\text{s-Encoding-rules} \wedge \\
\text{getEntityDefinition1}(p.\text{s-Destination-gate}, \mathbf{gate}).\text{s-Encoding-rules} = c.\text{s-Encoding-rules}
\end{aligned}$$

The *Originating-gate* or *Destination-gate* shall have the same *Encoding-rules* as the *Channel-definition*. If the *Channel-definition* has no *Encoding-rules*, neither the *Originating-gate* nor *Destination-gate* shall have *Encoding-rules*. See clause 10.1 *Abstract grammar* of [ITU-T Z.104]

## Concrete syntax

```

<channel definition> ::
  [<channel<name> [ <encoding rules>]] [nodelay] <channel path> [<channel path>]

<channel path> :: <channel endpoint> <channel endpoint> [ <signal list> ]

<channel endpoint> :: { <agent<identifier> | <state<identifier> | env | this } [<gate>]

<as channel> :: <channel<identifier>

```

## Conditions on concrete syntax

```

 $\forall ce \in \langle \text{channel endpoint} \rangle:$ 
let  $g = ce.\text{s-}\langle \text{gate} \rangle$  in
case  $id = ce.\text{s-implicit of}$ 
|  $\langle \text{identifier} \rangle$  then // agent identifier or state identifier
  case  $d = \text{getEntityDefinition0}(id, \mathbf{agent} \cup \mathbf{state})$  of
|  $\langle \text{textual typebased agent definition} \rangle \cup \langle \text{typebased composite state} \rangle$  then
  let  $td = d.\text{s-}\langle \text{type expression} \rangle.\text{baseType0}$  in
   $g \neq \text{undefined} \wedge$  // the gate is specified in the channel endpoint
   $(\exists gd \in \langle \text{textual gate definition} \rangle: \exists gc \in \langle \text{gate constraint} \rangle: //$  exists a gate definition and constraint
     $gd.\text{name0} = g \wedge$  // gate definition has the gate name
     $gd \in td.\text{localGateDefinitionSet0} \wedge$  // gate definition defined in the agent/state type
     $gc.\text{parentAS0} = gd \wedge$  // is a gate constraint of the gate definition
    // at least one common element in the signal lists
     $gc.\text{s-}\langle \text{signal list item} \rangle.\text{seq}.\text{signalSet0} \cap ce.\text{parentAS0}.\text{s-}\langle \text{signal list item} \rangle.\text{seq}.\text{signalSet0} \neq \emptyset \wedge$ 
     $gc.\text{direction0} = ce.\text{direction0} //$  in the same direction
  endlet // td
  otherwise true // agent/state machine not typebased, condition shall hold when transformed to typebased
  endcase // d
| env then // environment
  let  $su = ce.\text{surroundingScopeUnit0}$  in
   $su \in \langle \text{agent type definition} \rangle \Rightarrow$ 
   $g \neq \text{undefined} \wedge$  // the gate is specified in the channel endpoint
   $(\exists gd \in \langle \text{textual gate definition} \rangle: \exists gc \in \langle \text{gate constraint} \rangle: //$  exists a gate definition and constraint
     $gd.\text{name0} = g \wedge$  // gate definition has the gate name
     $gd \in su.\text{localGateDefinitionSet0} \wedge$  // gate definition defined in the agent type
     $gc.\text{parentAS0} = gd \wedge$  // is a gate constraint of the gate definition
    // at least one common element in the signal lists
     $gc.\text{s-}\langle \text{signal list item} \rangle.\text{seq}.\text{signalSet0} \cap ce.\text{parentAS0}.\text{s-}\langle \text{signal list item} \rangle.\text{seq}.\text{signalSet0} \neq \emptyset \wedge$ 
     $gc.\text{direction0} = ce.\text{direction0} //$  in the same direction
  endlet // su
| this then // the state machine of the enclosing agent
  let  $su = ce.\text{surroundingScopeUnit0}$  in
  let  $sm = su.\text{s-}\langle \text{agent structure} \rangle.\text{s-}\langle \text{interaction} \rangle.\text{s-}\langle \text{typebased composite state} \rangle$  in // the state machine

```

```

let td = sm.s-<type expression>.baseType0 in
  g ≠ undefined ∧ // the gate is specified in the channel endpoint
  (∃gd ∈ <textual gate definition>: ∃gc ∈ <gate constraint>: // exists a gate definition and constraint
    gd.name0 = g ∧ // gate definition has the gate name
    gd ∈ td.localGateDefinitionSet0 ∧ // gate definition defined in the state type
    gc.parentAS0 = gd ∧ // is a gate constraint of the gate definition
    // at least one common element in the signal lists
    gc.s-<signal list item>-seq.signalSet0 ∩ ce.parentAS0.s-<signal list item>-seq.signalSet0 ≠ ∅ ∧
    gc.direction0 = ce.direction0) // in the same direction
  endlet // td
  endlet // sm
  endlet // su
otherwise false // condition not met -
endcase // id
endlet // g

```

<gate> shall be specified if:

- a) <channel endpoint> with an <agent<identifier> denotes a connection to a <textual typebased agent definition> in which case the <gate> shall be defined directly in the agent type for that agent; or
- b) <channel endpoint> with a <state<identifier> identifies the state machine of the enclosing agent, in which case the <gate> shall be defined directly in the state type for that state, and as there is only one state machine it can alternatively be identified by **this**; or
- c) **env** is specified and the channel is defined in an agent type in which case the <gate> shall be defined in this agent type.

If gate is specified the channel is connected to that gate. The gate and channel shall have at least one common element in their signal lists in the same direction. See clause 5.6.1 of [ITU-T Z.106].

$$\forall c \in \langle \text{channel definition} \rangle:$$

$$(c.s1-\langle \text{channel path} \rangle.s-\langle \text{signal list} \rangle = \text{undefined} \Rightarrow c.s1-\langle \text{channel path} \rangle.derivedSignalList0 \neq \text{empty})$$

$$\wedge (c.s2-\langle \text{channel path} \rangle \neq \text{undefined}) \Rightarrow$$

$$c.s2-\langle \text{channel path} \rangle.s-\langle \text{signal list} \rangle = \text{undefined} \Rightarrow c.s2-\langle \text{channel path} \rangle.derivedSignalList0 \neq \text{empty})$$

If any associated <signal list> is omitted from the <channel path> of a <channel definition>, the corresponding set of signals shall be derivable. See clause 10.1 *Concrete grammar* of [ITU-T Z.103].

Derivation of an omitted channel <signal list> is possible if at least one <channel endpoint> identifies a <textual typebased agent definition> or <typebased composite state> (or **this** and the state machine is a <typebased composite state>) or **env**, and the gate for the <channel endpoint> has a defined set of signals in the direction for the <signal list>. The set of signals is defined for the gate if it identifies a <textual gate definition> that has a <gate constraint> with a defined <signal list>, or if a signal set is defined for all internal channels connected to this gate. The set is defined for a gate connected to <external channel identifiers> if for each external channel either no <signal list area> is omitted or the set for that external channel is derivable. See clause 5.6.1 of [ITU-T Z.106] which describes derivation for the textual grammar and is based on clause 10.1 *Concrete grammar* of [ITU-T Z.103].

## Transformations

$$\langle \text{channel definition} \rangle(\text{undefined}, \text{delay}, p1, p2)$$

$$=5\Rightarrow$$

$$\mathbf{mk}\text{-}\langle \text{channel definition} \rangle(\text{newName}, \text{delay}, p1, p2)$$

If the <channel name> is omitted from a <channel definition>, the channel is implicitly and uniquely named. See clause 10.1 *Model* of [ITU-T Z.103].

$$\langle \text{channel definition} \rangle(\text{name}, \text{delay}, p1, p2)$$

$$\mathbf{provided}$$

$$p1.s-\langle \text{signal list} \rangle = \text{undefined}$$

```

=8=>
mk-<channel definition>(
  name,
  delay,
  mk-<channel path>( p1.s1-<<channel endpoint>, p1.s2-<<channel endpoint>, p1.derivedSignalList0),
  p2)

<channel definition>(name, delay, p1, p2)
provided
  p2 ≠ undefined
  ^ p2.s-<signal list> = undefined
=13=>
mk-<channel definition>(
  name,
  delay,
  p1,
  mk-<channel path>( p2.s1-<<channel endpoint>, p2.s2-<<channel endpoint>, p2.derivedSignalList0)
)

```

If an associated <signal list> is omitted from a <channel definition>, the <signal list> is replaced by a <signal list> derived from the channel connection (see condition on <signal list> in a <channel definition> above), that corresponds to the *In-signal-identifier-set* or *Out-signal-identifier-set* for the *Destination-gate* or *Originating-gate*. Modified from clause 10.1 *Model* of [ITU-T Z.103].

NOTE 1 – This transform takes place after the transform of shorthand notations <agent definition>, <agent body> and <composite state definition> in step 12, so that the channel endpoint is typebased or **this** or **env**, and a gate has to be specified.

    missingConnections(a.parentAS0.parentAS0,a).take, undefined) in
    < a > ^ < c >
endlet

```

The text for the three transforms below is from clause 10.1 Model of [ITU-T Z.103].

If an agent or agent type contains explicit or implicit gates that are not attached by explicit channels, implicit channels are derived according to the following three transforms, which are applied after the transform for typebased creation is applied.

Transform 1:

Insertion of channels between instance sets inside the agent or agent type and between the instance sets and the agent state machine.

Transform 2:

Insertion of channels from a gate on the agent or agent type to gates on instance sets inside the agent or agent type and to gates on the agent state machine.

Transform 3:

Insertion of channels from gates on instance sets inside the agent or agent type and from gates on the agent state machine to gates on the agent or agent type.

In the transforms one signal list element (interface, signal, remote procedure or remote variable) matches another signal list element if:

- a) both denote the same interface, signal, remote procedure or remote variable; or
- b) the first denotes a signal or remote procedure or remote variable, and the second denotes an interface and the interface includes the signal or remote procedure or remote variable; or
- c) both denote interfaces and the second signal list element inherits the first signal list element.

Transform 1: Insertion of implicit channels between entities inside one agent or agent type

- a) If an element of the outgoing signal list associated with a gate of an instance in an agent (or agent type) matches an element of an incoming signal list associated with a gate of another instance in the same agent (or agent type respectively); and
  - b) if neither of these gates has an explicit channel attached to it,
- then

- a) if no implicit channel exists between the two gates, a unidirectional implicit channel is created from the gate where the element is outgoing to the gate where the element is incoming, and this channel is non-delaying if it is within a process (or process type) and otherwise it is delaying; and
- b) the element is added to the signal list of the implied channel.

Transform 2: Insertion of implicit channels from the gates on an agent or agent type

- a) If an element of the incoming signal list associated with a gate outside an agent (or agent type) matches an element of an incoming signal list associated with a gate of an instance in the agent (or agent type respectively); and
- b) if there is no explicit channel inside the agent (or agent type respectively) attached to the gate outside the agent (or agent type respectively) and no explicit channel attached to the gate of the instance inside the agent (or agent type respectively),

then

- a) if no implicit channel exists between the two gates, a unidirectional implicit channel is created from the gate outside the agent (or agent type respectively) to the gate of the instance inside the agent (or agent type respectively), and this channel is non-delaying if it is within a process (or process type) and otherwise it is delaying; and
- b) the element is added to the signal list of the implied channel.

Transform 3: Insertion of implicit channels from the gates on instances

The following is applied for insertion of implicit channels from the gates on instance sets within the agent or agent type to the gates on the agent or agent type:

- a) If an element of the outgoing signal list associated with a gate outside an agent (or agent type) matches an element of an outgoing signal list associated with a gate of an instance in the agent (or agent type respectively); and
- b) if there is no explicit channel attached to the gate outside the agent (or agent type respectively) and no explicit channel connected to the gate of the instance inside the agent (or agent type respectively),

then

- a) if no implicit channel exists between the two gates in the direction to the gate outside the agent (or agent type respectively), a unidirectional implicit channel is created from the gate of the instance inside the agent (or agent type respectively) to the gate outside the agent (or agent type respectively), and this channel is non-delaying if it is within a process (or process type) and otherwise it is delaying; and
- b) the element is added to the signal list of the implied channel.

*The following statement is modelled in the dynamic semantics.*

A channel with both endpoints being gates of one <textual typebased agent definition> represents individual channels from each of the agents in this set to all agents in the set, including the originating agent. Any resulting bidirectional channel connecting an agent in the set to the agent itself is split into two unidirectional channels. Modified from clause 10.1 *Model* of [ITU-T Z.103].

*cd.asChannelName*

**provided**

*cd* ∈ <channel definition>

∧ *cd.asChannelName* = *undefined*

=8=>

(*asChannelName* \{( *cd*, *undefined* )} ) ∪ {( *cd*, *newName* )}

NOTE 2 – Each <channel definition> defines a *Data-type-definition* of a choice data type with a unique anonymous *Sort* name stored in *asChannelName*.

<as channel>(cid)

**provided**

*cid.refersto0.asChannelName* ≠ *undefined*

=8=>

**mk**-<type expression>(mk-<identifier>(cid.s-<qualifier>, *cid.refersto0.asChannelName*), *undefined*)

An <as channel> represents the sort of the choice data type introduced by the identified channel definition. See clause 12.1 *Concrete grammar* of [ITU-T Z.104].

## Mapping to abstract syntax

```
| <channel definition>(name, encoding, delayProperty, path1, path2) then
  mk-Channel-definition(Mapping(name),
    if encoding ≠ undefined
    then Mapping(encoding)
    else // encoding rules omitted in channel definition
      if path1.pathEncodings0 ≠ undefined then Mapping(path1.pathEncodings0)
      else
        if path2 ≠ undefined
        then
          if path2.pathEncodings0 ≠ undefined then Mapping(path2.pathEncodings0)
          else undefined
          endif // path2 encoding defined/undefined
        else undefined
        endif // path2 defined/undefined
      endif // path1 encoding defined/undefined
    endif, // encoding rules in channel definition
    if delayProperty = nodelay then NODELAY else undefined endif,
    if path2=undefined
    then { Mapping(path1) }
    else { Mapping(path1), Mapping(path2) }
    endif)
```

If the <encoding rules> item is omitted in a <channel definition> and a <channel path> is connected to a <gate> that identifies a <gate definition> with <encoding rules>, the *Channel-definition* has the same *Encoding-rules* as the *Gate-definition* of the <textual gate definition>. If the *Gate-definition* has no *Encoding-rules*, the *Channel-definition* has no *Encoding-rules*. Derived from See clause 10.1 *Model* of [ITU-T Z.104].

NOTE 3 – The mapping to a *Data-type-definition* for the choice data type defined by a <channel definition> in the following paragraph takes place by invoking the function *choiceForChannel1* (defined below), in the mapping to *Agent-type-definition* in clauses F2.2.5.1.2, F2.2.5.1.3 and F2.2.5.1.4.

A *Channel-definition* implicitly defines a *Data-type-definition* of a choice data type with a unique anonymous *Sort* name in the context that the *Channel-definition* is visible. A <basic sort> that is <as channel> where <channel<identifier> identifies the *Channel-definition* represents this *Data-type-definition*. The *Data-type-definition* is equivalent to defining a choice data type with a <choice of sort> for each distinct *Signal-definition* identified by each *Signal-identifier-set* of the *Channel-path-set*. The <field name> and <field sort> for each <choice of sort> is determined in the same way as a <choice of sort> for each distinct *Signal-definition* of the *Data-type-definition* defined by a <gate definition>. See clause 10.1 *Concrete grammar* of [ITU-T Z.104].

```
| <channel path>(endp1(*, g1), endp2(*, g2), with) then
  mk-Channel-path(Mapping(endp1), Mapping(g1), Mapping(endp2), Mapping(g2), Mapping(with))

| <channel endpoint>( end, *) then
  mk-Channel-endpoint(
    case end of
    | <identifier> then Mapping(end)
    | env then ENV
    | this then
      let atd = parentAS0ofKind(end,
        <system type definition> ∪ <block type definition> ∪ <process type definition>)
      in
      mk-Identifier(Mapping(atd.identifier0.s-<qualifier>) ^
        < mk-Agent-type-qualifier(Mapping(atd.identifier0.s-<name> ) >,
          Mapping(atd.s-<agent structure>.s-<interaction>.s-<state machine>.s-<name>))
```

```

    endlet
  endcase)

```

## Auxiliary functions

$SIGNALDIRECTION0 =_{def} \{ \mathbf{out}, \mathbf{in} \}$

Get the direction of a <gate constraint> or a <channel endpoint>.

```

direction0(p: <gate constraint> ∪ <channel endpoint>): SIGNALDIRECTION0 =_{def}
  case p of
  | <channel endpoint> then if p=p.parentAS0.s1-<channel endpoint> then out else in endif
  | <gate constraint> then if p.s-in ≠ undefined then in else p.s-out endif // s-out could be undefined
  otherwise undefined
  endcase

```

The function *channelEndpointReferTo0* is used to get the entity definition that the <channel endpoint> referred to.

```

channelEndpointReferTo0(ep:<channel endpoint>): ENTITYDEFINITION0 =_{def}
  let end = ep.s-implicit in
  case end of
  | <identifier> then getEntityDefinition0(end, end.idKind0)
  | this then parentAS0ofKind(end, <agent definition> ∪ <agent type definition> )
  | env then undefined
  endcase
  endlet

```

The function *unconnectedGates* is used to store the gates that are not explicitly connected.

```

controlled unconnectedGates: <textual typebased agent definition> ∪ <agent type definition> →
  <gate in definition>-set
initially ∇ def ∈ (<textual typebased agent definition> ∪ <agent type definition>):
  def.unconnectedGates = undefined

```

The function *missingConnections* is used to compute the missing implicit connections between two agents.

```

missingConnections(ag1: <textual typebased agent definition> ∪ <agent type definition>,
  ag2: <textual typebased agent definition> ∪ <agent type definition>): <channel path>-set =_{def}
  let entities =
    if ag1 ∈ <agent type definition> then ag1.getEntities0
    elseif ag2 ∈ <agent type definition> then ag2.getEntities0
    else parentAS0ofKind(ag1, <agent type definition>).getEntities0
    endif
  in
  let id1 =
    if ag1 ∈ <agent type definition> then env else ag1.identifier0 endif
  in
  let id2 =
    if ag2 ∈ <agent type definition> then env else ag2.identifier0 endif
  in
  U { { mk-<channel path>(
    mk-<channel endpoint>(id1, g1),
    mk-<channel endpoint>(id2, g2),
    <siglistitem ∈ (inoutSignals0(g1, out) ∪ inoutSignals0(g2, in)) > ) // channel path
    : g2 ∈ ag2.unconnectedGates ∧ ((inoutSignals0(g1, out) ∪ inoutSignals0(g2, in)) ≠ ∅) ∧
    ¬isConnected(g1, g2, entities) }
    : g1 ∈ ag1.unconnectedGates }
  endlet // id2
  endlet // id1
  endlet // entities

```

The function *isConnected* is used to check whether two gates are connected.

```

isConnected(g1:<gate in definition>, g2: <gate in definition>, ent: DefinitionAS0-set): BOOLEAN =def
let allPaths =
  U { { e.s1-<channel path> } ∪
    if e.s2-<channel path> = undefined then ∅ else { e.s2-<channel path> } endif
    | e ∈ ent.toSet: e ∈ <channel definition> }
in
  ∃ p ∈ allPaths: g1=p.s1-<channel endpoint>.s-<gate>.refersto0 ∧
    (g2=p.s2-<channel endpoint>.s-<gate>.refersto0 ∨ g2 = undefined)
endlet // allPaths

```

The function *inoutSignals0* is used to compute the outbound or inbound signals of a gate based on the <gate constraint>.

```

inoutSignals0(g: <textual gate definition>, kind: SIGNALDIRECTION0): <signal list item>-set =def
if kind: = in then
  { sli : sli in gc.s1-<signal list item>-seq ∧ gc ∈ g.s-<gate constraint> ∧ gc.direction0 = in }
else // kind is out
  { sli : sli in gc.s2-<signal list item>-seq ∧ gc ∈ g.s-<gate constraint> ∧ gc.direction0 = in } ∪
  { sli : sli in gc.s1-<signal list item>-seq ∧ gc ∈ g.s-<gate constraint> ∧ gc.direction0 = out }
endif // kind

```

The function *pathEncodings0* is used to get the encoding rules (if any) specified by one of gates (if any) at the channel endpoints of the path. If both channel endpoints have a gate with encoding rules, these rules are required to be the same.

```

pathEncodings0(cp: <channel path>): <encoding rules> =def
let localQualifier = cp.surroundingScopeUnit0.fullQualifierWithin0 in
let g1 = cp.s1-<channel endpoint>.s-<gate> in
let g2 = cp.s2-<channel endpoint>.s-<gate> in
if g1 ≠ undefined then
  let rules1 = mk-<identifier>(localQualifier,g1).refersto0.s-<encoding rules> in
  if rules1 ≠ undefined then rules1
  else
    if g2 ≠ undefined then mk-<identifier>(localQualifier,g2).refersto0.s-<encoding rules>
    else undefined // g2 undefined, g1 defined but no encoding rules
    endif // rules2 undefined
  endif
endlet // rules1
else // g1 undefined
  if g2 ≠ undefined then
    let rules2 = mk-<identifier>(localQualifier,g2).refersto0.s-<encoding rules> in
    if rules2 ≠ undefined then rules2 else undefined endif
    endlet // rules2
  else undefined // g1 undefined and g2 undefined
endif
endlet // g2
endlet // g1
endlet // localQualifier

```

The function *choiceForChannel1* produces the choice *Data-type-definition* that corresponds to a *Channel-definition* and is used when an <as channel> is given for a <basic sort>, where each <choice of sort> is for each distinct signal definition identified by each signal identifier that is a signal list item of the signal list of a channel path of the channel definition.

```

choiceForChannel1(cd: <channel definition>): Data-type-definition =def
let chanSigSet =
  { sig : sig in cd.s1-<channel path>.s-<signal list item>-seq
    ∨ ( cd.s2-<channel path> ≠ undefined
      ^

```

```

    sig in cd.s2-<channel path>.s-<signal list item>-seq
  )
} // chanSigSet
in
Mapping(mk-<data type definition>( mk-<type preamble>(undefined, undefined), // type preamble
  mk-<data type heading>( cd.asChannelName, // name for choice type
    undefined, undefined, // no formal parameters or virtuality constraint
  ), // data type heading
  mk-<data type definition body>( empty, // no entities in data type
    mk-<choice definition>( undefined, // visibility
      < mk-<choice of sort>( undefined, // visibility
        mk-<field of kind>( part,
          if sig.s-<name> ∉ { othersigs.s-<name>
            : othersigs ∈ (chanSigSet \ sig )}
          then // unique signal name
            sig.s-<name>
          else // not unique signal name – name same as <as signal>
            sig.asSignal.s-<name>// name of structure sort for signal
          endif
        ), // <field of kind>
        mk-<field sort>(
          if sig.refersto0.s-implicit // <sort list> | <named fields sort list> | <sort><identifier>
            = undefined // no sort
          then predefinedId0("NULL")
          else sig.asSignal // structure sort for signal
          endif
        ) // <field sort>
      ) // <choice of sort> item
    : sig ∈ chanSigSet
  > // <choice of sort> list
  ) <choice definition>(
  ), // data type definition body
  undefined // default initialization
)) // Mapping of data type definition
endlet // chanSigSet

```

The function *derivedSignalList0* produces a derived list of signal <identifier> items, to be used in a <channel path> of a <channel definition> when a <signal list> is omitted from the <channel path> of a <channel definition>. The description of the derivation is in the text for the condition for the missing <signal list> items to be derivable.

```

derivedSignalList0(cp: <channel path>): <signal><identifier>* =def
let orig = cp.s1-<channel endpoint> in
let origgate = orig.s-<gate> in
let origgateDef =
  case orig.s-implicit of // first item of channel endpoint
  | <identifier> then mk-<identifier>(orig.s-implicit.refersto0.fullQualifierWithin0, origgate).refersto0
  | this then

else // signals not derivable
  empty
endif
endlet // destgateDef
endlet // destgate
endlet // dest
endlet // origgateDef
endlet // origgate
endlet // orig

```

The function *connectedChanSet* produces a set of channels connected to a channel endpoint in the agent identified by the channel endpoint in the forward (or reverse) direction.

```

connectedChanSet(ce: <channel endpoint>, forward: BOOLEAN): <channel definition>-set =def
{ ch : ch ∈ <channel definition> // channels
  ∧ ce.s-implicit.refersto0 = ch.surroundingScopeUnit0 // ch internal to agent at ce
  ∧ if forward
    then // forward paths
      ch.s1-<channel path>.s2-<channel endpoint>.s-implicit = env // to env
      ∧ ch.s1-<channel path>.s2-<channel endpoint>.s-<gate> = ce.s-<gate> // via ce
    else // reverse paths
      ch.s2-<channel path> ≠ undefined // reverse path defined
      ∧ ch.s2-<channel path>.s2-<channel endpoint>.s-implicit = env // to env
      ∧ ch.s2-<channel path>.s2-<channel endpoint>.s-<gate> = ce.s-<gate> // via ce
    endif
} // all internal channels connected to ce with forward (reverse) path

```

The function *asChannelName* associates each <channel definition> with a unique anonymous name for the *Sort* of the corresponding *Data-type-definition* of the choice data type invoked by <as channel>.

```

controlled asChannelName: <channel definition> → <name>
initially ∀ cd ∈ <channel definition>: cd.asChannelName = undefined

```

## F2.2.7.2 Connections

### Concrete syntax

```

<channel to channel connection> ::
  <external channel identifiers> <channel><identifier>+
<external channel identifiers> = <channel><identifier>+

```

### Conditions on concrete syntax

```

∀ c2c ∈ <channel to channel connection>: c2c.surroundingScopeUnit0 ∉ <agent type definition>

```

A <channel to channel connection> shall not be directly contained within an <agent type definition>. See clause 5.5 of [ITU-T Z.106].

```

 $\forall c1, c2 \in \langle \text{channel to channel connection} \rangle$ :
  ( let  $ids1 = c1.s2$ -<identifier>-seq.toSet in
    let  $ids2 = c2.s2$ -<identifier>-seq.toSet in
       $c1.surroundingScopeUnit0 = c2.surroundingScopeUnit0 \wedge c1 \neq c2 \Rightarrow ids1 \cap ids2 = \emptyset$ 
    endlet
  endlet)

```

It is not allowed to mention a channel after the keyword **and** in more than one <channel to channel connection> of a given scope unit. See clause 5.6.2 of [ITU-T Z.106].

```

 $\forall c1, c2 \in \langle \text{channel to channel connection} \rangle$ :
  (let  $ids1 = c1.s$ -<identifier>-seq.toSet in
    let  $ids2 = c2.s$ -<identifier>-seq.toSet in
      ( $c1.surroundingScopeUnit0 = c2.surroundingScopeUnit0 \wedge c1 \neq c2$ )
       $\Rightarrow (ids1 = ids2 \vee ids1 \cap ids2 = \emptyset)$ 
    endlet
  endlet)

```

For any pair of <channel to channel connection> items of a given scope unit, the <external channel identifiers>s shall either mention the same set of channels, or shall have no channels in common. See clause 5.6.2 of [ITU-T Z.106].

## Transformations

```

ctcc.myImplicitGateIdentifier
provided
   $ctcc \in \langle \text{channel to channel connection} \rangle$ 
 $\wedge ctcc.myImplicitGateIdentifier = \text{undefined}$ 
 $\Rightarrow$ 
  (myImplicitGateIdentifier \{ ( ctcc, undefined ) \} )
 $\cup \{ ( ctcc, \mathbf{mk}$ -<identifier>(surroundingQualifier0(ctcc), newName) ) \}
```

```

 $ctcc = \langle \text{channel to channel connection} \rangle (*, *)$ 
provided
 $ctcc.myImplicitGateIdentifier \neq \text{undefined}$ 
 $\Rightarrow$ 
 $\mathbf{mk}$ -<textual gate definition>( ctcc.myImplicitGateIdentifier.s-<name>, undefined, // name, no encoding rules
  if  $allSignalsIn(ctcc).length > 1$  then
    if  $allSignalsOut(ctcc).length > 1$  then
       $\mathbf{mk}$ -<gate constraint>( in,  $allSignalsIn(ctcc)$ , out,  $allSignalsOut(ctcc)$  )
    else
       $\mathbf{mk}$ -<gate constraint>( in,  $allSignalsIn(ctcc)$ , undefined )
    endif
  else
    if  $allSignalsOut(ctcc).length > 1$  then
       $\mathbf{mk}$ -<gate constraint>( out,  $allSignalsOut(ctcc)$  )
    else  $\mathbf{mk}$ -<gate constraint>( undefined ) // should not occur
    endif
  )
and
 $cendpt = \langle \text{channel endpoint} \rangle (id, \text{undefined})$ 
provided
 $findconnect(cendpt.parentAS0.parentAS0, id) \neq \text{undefined}$ 
 $\Rightarrow$ 
 $\mathbf{mk}$ -<channel endpoint>( id,  $findconnect(cendpt.parentAS0.parentAS0, id)$  )

```

Each different <channel to channel connection> in a given scope unit defines one implicit gate on the scope unit. All channels in the <channel to channel connection> are connected to that gate in their respective scope units. The gate constraints of the implicit gate are derived from the channels connected to the gate. The name of the gate is a unique and unambiguous derived name. In the surrounding scope unit the <channel definition> that is identified by the <channel identifier> is extended with a **via** <gate> part. The **via** <gate> part is added to the <channel endpoint> that

references the current scope unit and it mentions the implicit gate. Inside the scope unit the channels that are associated with the external channel by means of the <channel to channel connection> are modified, by extending the <channel endpoint> that mentions **env** with a **via** <gate> part for the implicit gate. See clause 5.6.2 of [ITU-T Z.106].

### Auxiliary functions

The auxiliary function *myImplicitGateIdentifier* stores the implicitly generated gate identifier of a connection.

```
controlled myImplicitGateIdentifier: <channel to channel connection> → <identifier>
initially ∇ ctcc ∈ <channel to channel connection>: ctcc.myImplicitGateIdentifier = undefined
```

The function *findconnect* computes the implicit gate identifier for a channel that is mentioned in a channel-to-channel connection.

```
findconnect(ch:<channel definition>, id: DefinitionAS0): <identifier> =def
if id=env then
  let matchingGateIds =
    { c.myImplicitGateIdentifier | c ∈ <channel to channel connection>:
      c.parentAS0 = ch.parentAS0 ∧ fullIdentifier0(ch) in c.s2-<identifier>-seq }
  in
    matchingGateIds.take
  endlet // matchingGateIds
else
  let matchingGateIds =
    { c.myImplicitGateIdentifier | c ∈ <channel to channel connection>:
      c.parentAS0 = id.refersto0 ∧ fullIdentifier0(ch) in c.s-<identifier>-seq }
  in
    matchingGateIds.take
  endlet // matchingGateIds
endif
```

The function *allSignalsIn* computes the input signals belonging to a channel-to-channel connection.

```
allSignalsIn(c: <channel to channel connection>): <signal list item>* =def
setToSeq(toSet // removes duplicate signal list items
  bigSeq( < // all external channels to scope round ctcc, or from scope round ctcc
    if extchan.refersto0.s1-<channel path>.s2-<channel endpoint> = ctcc.surroundingScopeUnit0
    then extchan.refersto0.s1-<channel path>.s-<signal list item>-seq
    elseif extchan.refersto0.s2-<channel path> ≠ undefined
    then extchan.refersto0.s2-<channel path>.s-<signal list item>-seq
    else empty
    endif // external channels to/from scope round ctcc
  : extchan in ctcc.s1-<identifier>-seq // external channels of ctcc
  > ) // list of signal list item lists, bigSeq – which flattens the list of lists
  )
  bigSeq(
    < // all internal channels from env to something, or from something to env
    if intchan.refersto0.s1-<channel path>.s1-<channel endpoint> = env
    then intchan.refersto0.s1-<channel path>.s-<signal list item>-seq
    elseif intchan.refersto0.s2-<channel path> ≠ undefined
    then intchan.refersto0.s2-<channel path>.s-<signal list item>-seq
    else empty
    endif // all internal channels to/from env
  : intchan in ctcc.s2-<identifier>-seq // internal channels of ctcc
  > ) // list of signal list item lists, bigSeq – which flattens the list of lists
  ) // toSet make the sequence into a set, setToSeq make the set into (random) sequence
```

The function *allSignalsOut* computes the output signals belonging to a channel-to-channel connection.

```

allSignalsOut(ctcc: <channel to channel connection>): <signal list item>* =def
setToSeq(toSet( // removes duplicate signal list items
  bigSeq( < // all external channels from scope round ctcc, or to scope round ctcc
    if extchan.refersto0.s1-<channel path>.s1-<channel endpoint> = ctcc.surroundingScopeUnit0
    then extchan.refersto0.s1-<channel path>.s-<signal list item>-seq
    elseif extchan.refersto0.s2-<channel path> ≠ undefined
    then extchan.refersto0.s2-<channel path>.s-<signal list item>-seq
    else empty
    endif
  : extchan in ctcc.s1-<identifier>-seq // external channels of ctcc
  > ) // list of signal list item lists, bigSeq – which flattens the list of lists
  ~
  bigSeq(
  < // all internal channels from env to something, or from something to env
  if intchan.refersto0.s1-<channel path>.s1-<channel endpoint> = env
  then
    if intchan.refersto0.s2-<channel path> ≠ undefined
    then intchan.refersto0.s2-<channel path>.s-<signal list item>-seq
    else empty
    endif
  else intchan.refersto0.s1-<channel path>.s-<signal list item>-seq
  endif
  : intchan in ctcc.s2-<identifier>-seq // internal channels of ctcc
  > ) // list of signal list item lists, bigSeq – which flattens the list of lists
  ) ) // toSet make the sequence into a set, setToSeq make the set into a (random) sequence

```

### F2.2.7.3 Signal

#### Abstract syntax

```

Signal-definition      ::      Signal-name
                          Signal-parameter*
                          [ Signal-identifier ]
                          [ Abstract ]

Signal-parameter       ::      Aggregation-kind Sort-reference-identifier

```

#### Concrete syntax

```

<signal definition list> :: <signal definition>+
<signal definition> :: <type preamble>
                     <signal name>
                     [ <formal context parameters> ]
                     [ <virtuality constraint> ]
                     [ <specialization> ]
                     [ <sort list> | <named fields sort list> | <sort identifier> ]

<named fields sort list> :: [ <visibility> ]
                          { [ <visibility> ] <aggregation kind> <field name> <sort> }+

<sort list> :: { <aggregation kind> <sort> }+
<as signal> :: <signal identifier>

```

#### Conditions on concrete syntax

$\forall sdi \in \langle \text{signal definition} \rangle: sdi.\text{specialization0.s} \langle \text{type expression} \rangle .s \langle \text{base type} \rangle .idKind0 = \mathbf{signal}$

The  $\langle \text{base type} \rangle$  part of  $\langle \text{specialization} \rangle$  shall be a  $\langle \text{signal identifier} \rangle$ . See clause 12.3 *Concrete grammar* of [ITU-T Z.102].

$\forall sid \in \langle \text{identifier} \rangle:$   
 $sid.\text{parentAS0} \notin \langle \text{type expression} \rangle \wedge sid.\text{parentAS0} \notin \langle \text{signal constraint} \rangle \Rightarrow$   
 $\neg \text{getEntityDefinition0}(sid, \mathbf{signal}).\text{isAbstractType0}$

An abstract type shall not be instantiated. See clause 8.1.3 *Semantics* of [ITU-T Z.102]. As a consequence, an abstract signal can only be used in specialization and signal constraints.

```

∀sdi ∈ <signal definition>:
  sdi.s-implicit ∈ <identifier> ⇒ // sort identifier
  sdi.s-implicit.refersto0.derivedDataType0.s-<data type definition body>.s-<data type constructor>
    ∈ <structure definition>

```

The <sort-identifier> of **struct** <sort-identifier> of a <signal definition> shall identify the sort of a structure data type. See clause 10.3 *Semantics* of [ITU-T Z.104].

## Transformations

```

<signal definition list>( itemlist ) provided itemlist.length > 1
=5=>
if itemlist.length > 1
then mk-<signal definition list>( < itemlist.head > ) ^ mk-<signal definition list>( itemlist.tail )
else mk-<signal definition list>( < itemlist.head > ) // only one item in list
endif

```

If several <signal definition> items are specified in one <signal definition list>, this is equivalent to individual <signal definition list>s for each of them. See clause 10.3 *Concrete grammar* of [ITU-T Z.101].

```

sigId.asSignal
provided
sigId.asSignal = undefined ∧
sigId ∈ { id ∈ <identifier>: id.refersto0 ∈ <signal definition> }
=5=>
case sortlist = sigId.refersto0.s-implicit of // sortlist
| undefined then // parameterless signal
  (asSignal\{( sigId, undefined ) } ) ∪ {( sigId, mk-<identifier>( sigId.s-<qualifier>, newName))}
| (<sort list> ∪ <named fields sort list>) then
  (asSignal\{( sigId, undefined ) } ) ∪ {( sigId, mk-<identifier>( sigId.s-<qualifier>, newName))}
| <identifier> then // sortlist = sort identifier
  (asSignal\{( sigId, undefined ) } ) ∪ {( sigId, sortlist ) }
endcase // sortlist

```

The following three paragraphs from clause 10.3 *Concrete grammar* of [ITU-T Z.104], describes the implicit type associated (as above) with a <signal definition> by the function *asSignal* and mapped to the abstract syntax as described below.

A <signal definition> that defines a *Signal-definition* with an empty *Signal-parameter* list (a signal definition) without a <sort list> or <named fields sort list> or **struct** <sort identifier>, defines in the same context as the *Signal-definition* a *Syntype-definition* with a unique anonymous *Syntype-name*, NULL, as the *Parent-sort-identifier*, and empty *Range-condition* and no *Default-initialization*. In this case, an <as signal> (for the signal definition) when used as a <basic sort> denotes the data type NULL.

A <signal definition> that defines a *Signal-definition* with a non-empty *Signal-parameter* list defined by a <sort list> or <named fields sort list>, defines in the same context as the *Signal-definition* a *Data-type-definition* for a structure data type with a unique anonymous *Sort* name. In this case, an <as signal> (for the signal definition) when used as a <basic sort> denotes the *Sort* of the *Data-type-definition*. The *Data-type-definition* is equivalent to defining a structure data type with an **optional** <field> for each <aggregation kind> and <sort> item (in order) of the <sort list> or <named fields sort list>, where the <aggregation kind> and <field sort> is the same as those of the <sort list> or <named fields sort list>. If the <signal definition> has a <sort list>, each field has a unique anonymous name and therefore has to be identified using a <field number> and the field present operation is not accessible because its name is unknown. If the <signal definition> has a <named fields sort list>, each <field> has the name given by the <field name> of the <named fields sort list> item.

For a <signal definition> that defines a *Signal-definition* with a non-empty *Signal-parameter* list defined by **struct** <sort identifier>, an <as signal> (for the signal definition) when used as a <basic sort> denotes the same *Sort* as the <sort identifier> of **struct** <sort identifier>.

## Mapping to abstract syntax

```
| <signal definition list>(< item >) then Mapping(item)

| sd = <signal definition>(*, name, *, *, *, sortlist) then
// type preamble virtuality/virtuality constraint ignored – type preamble abstract derived from sd
// specialization derived from sd: formal params not used here
if sortlist ∈ <identifier>
then // sortlist is a structure identifier
    mk-Signal-definition(Mapping(name),
        let structfields =
            derivedDataType0(sortlist.refersto0
                ).s-<data type definition body>.s-<data type constructor>.s-<field list>
        in
            < mk-Signal-parameter(
                Mapping(structfields[i].s-implicit.s-<fields of sort>.s-<field of kind>.head.s-<aggregation kind>),
                Mapping(structfields[i].s-implicit.s-<fields of sort>.s-<field sort>)
            ) // Signal-parameter
            : i ∈ 1..structfields.length
            > // list of Signal-parameters
        endlet // structfields
        Mapping(sd.specialization0.s-<type expression>.baseType0),
        if isAbstractType0(sd) then Abstract else Undefined endif
    ) // Signal-definition
else // sortlist is not a structure identifier – and there is a Signal-definition
    mk-Signal-definition(Mapping(name),
        if sortlist= undefined
        then empty
        else // sortlist is a sort list or a named sort list – sort identifier handled above
            < mk-Signal-parameter(
                Mapping(sortlist[i].s-<aggregation kind>),
                Mapping(sortlist[i].s-<sort>))
            : i ∈ 1..sortlist.length > // list of Signal-parameters
        endif,
        Mapping(sd.specialization0.s-<type expression>.baseType0),
        if isAbstractType0(sd) then Abstract else Undefined endif
    ) // Signal definition followed by data type definition
endif // sortlist
```

## Auxiliary functions

The function *typeForSignal1* produces the *Data-type-definition* or *Syntype-definition* that corresponds to a *Signal-definition* used when an <as signal> is given for a <basic sort> and the signal parameters are not defined by a structure sort identifier.

```
typeForSignal1(sd: <signal definition>): Data-type-definition ∪ Syntype-definition =def
let params = sd.s-implicit in
if params = undefined then
    mk-Syntype-definition(sd.identifier0.asSignal, // Syntype name
        predefinedId0("NULL"), // NULL as the Parent-sort-identifier,
        mk-Range-condition(∅), // empty Range-condition
        undefined // default initialization
    ) // Syntype definition
elseif params ∈ (<sort list> ∪ <named fields sort list>) //
    Mapping(
        mk-<data type definition>(
            mk-<type preamble>(undefined), // type preamble
            mk-<data type heading>(sd.identifier0.asSignal.s-<name>),
```

```

    undefined, undefined, // no formal parameters or virtuality constraint
), // data type heading
mk-<data type definition body>( empty, // entity in data type list
mk-<data type constructor>(
    mk-<structure definition>( undefined, // visibility of structure
    < mk-<optional field>(mk-<fields of sort>(undefined, // visibility of field
    < mk-<field of kind>(params[i].s-<aggregation kind>,
    if params ∈ <sort list> then newName else params[i].s-<name> endif)
    >,
    params[i].s-<sort>)):// fields of sort, optional field
    i ∈ 1..params.length
    > // list of fields
    ) // structure definition
), // data type constructor
mk-<operations>(
    mk-<operation signatures>( undefined, undefined), mk-<operation definitions>( empty )
), // operations
undefined // default initialization
) // data type definition body
) // data type definition
) // Mapping (of data type definition)
else // params is structure id
    undefined // no extra data type needs to be defined
endif
endlet // params

```

The function *asSignal* is used to store the identifier of the (possibly anonymous) data type or syntype corresponding to a signal definition.

```

controlled asSignal: <identifier> → <identifier> // signal identifier to sort identifier
initially ∇ sigId ∈ {id ∈ <identifier>: id.refersto0 ∈ <signal definition>}: sigId.asSignal = undefined

```

The function *asSignal1* is used to make the data type *Identifier* for <as signal> available to F3.

```

asSignal1(id1: Identifier ): Identifier // signal Identifier to sort Identifier
take({Mapping(asSignal(id0)) : Mapping(id0) = id1 ∧ id0.refersto0 ∈ <signal definition>})

```

#### F2.2.7.4 Signal list definition

##### Concrete syntax

```

<signal list definition> ::
    <interface<name> <signal list>

<signal list> =
    <signal list item>+

<signal list item> ::
    <signal<identifier>
    | <timer<identifier>
    | <interface<identifier>
    | <remote procedure<identifier>
    | <remote variable<identifier>

```

##### Transformations

```

<signal list definition>(n, sl)
=8=>
<interface definition>(empty, undefined,
    <interface heading>(n, empty, undefined), undefined, <entity in interface>(<interface use list>(sl)))

```

A <signal list definition> is an alternative concrete syntax, and is transformed into an <interface definition> using the keyword **interface** with no <package use clause>, no <virtuality>, an <interface heading> containing the <interface name> (but no <formal context parameters> or <virtuality

constraint>), no <interface type expression> specialization and no <entity in interface>. The <interface definition> has an <interface use list> with a <signal list> that is the same as the <signal list> of the <signal list definition>. See clause 12.1.2 *Model* of [ITU-T Z.103].

## Mapping to abstract syntax

| <<signal list item>( *id* ) > **then** *Mapping(id)*

### F2.2.7.5 Remote procedures

#### Concrete syntax

```

<remote procedure definition> ::
    <remote procedure><name> <procedure signature>
<remote procedure call> :: <remote procedure call body>
<remote procedure call body> ::
    <remote procedure><identifier> [ <actual parameters> ] <communication constraints>
<timer communication constraint> ::
    <timer><identifier> [ <variable> ]* [ <connector><name> ]

```

#### Conditions on concrete syntax

See clause 10.5 *Concrete grammar* [ITU-T Z.102] unless another reference is given.

```

 $\forall pd \in \langle \text{procedure definition} \rangle$ :
    let rpi = pd.s-<procedure heading>.s-<procedure preamble>.s-<exported>.s-<identifier> in
    let rp = getEntityDefinition0(rpi, remote procedure) in
        pd.isExported0  $\wedge$  rpi  $\neq$  undefined  $\Rightarrow$ 
            isSameProcedureAndSignature0(pd, rp.s-<procedure signature>)
    endlet // rp
    endlet // rpi

```

The <remote procedure identifier> following **as** in an exported procedure definition shall denote a <remote procedure definition> with the same signature as the exported procedure. See clause 9.4 *Concrete grammar* [ITU-T Z.102].

```

 $\forall pd \in \langle \text{procedure definition} \rangle$ :
    let rpi = pd.s-<procedure heading>.s-<procedure preamble>.s-<exported>.s-<identifier> in
    let rp = resolveByContainer0(pd.surroundingScopeUnit0,
        mk-<identifier>(empty, pd.name0),
        remote procedure)
    in
        pd.isExported0  $\wedge$  rpi = undefined  $\Rightarrow$ 
            (rp  $\neq$  undefined  $\wedge$  isSameProcedureAndSignature0(pd, rp.s-<procedure signature>))
    endlet // rp
    endlet // rpi

```

In an exported procedure definition with no **as** clause, there shall be a <remote procedure definition> in a surrounding scope with the same name and signature as the exported procedure and the nearest such <remote procedure definition> is used. See clause 9.4 *Concrete grammar* [ITU-T Z.102].

```

 $\forall rpc \in \langle \text{remote procedure call} \rangle$ :
    let d = parentAS0ofKind(rpc, <agent definition>  $\cup$  <agent type definition>) in
        rpc.s-<identifier>  $\in$  d.validOutputSignalSet0
    endlet

```

A remote procedure mentioned in a <remote procedure call body> shall be in the complete output set of an enclosing agent type or agent set.

```

 $\forall rpcb1, rpcb2 \in \langle \text{remote procedure call body} \rangle$ :
    let action1 = parentAS0ofKind(rpcb1, <action>) in
    let action2 = parentAS0ofKind(rpcb2, <action>) in
        parentAS0(rpcb1)  $\notin$  { <remote procedure call>  $\cup$  <call statement> } // is <expression0>

```

```

 $\wedge$   $parentAS0(rpcb2) \notin \{ \langle \text{remote procedure call} \rangle \cup \langle \text{call statement} \rangle \}$  // is  $\langle \text{expression0} \rangle$ 
 $\wedge$   $rpcb1.s\text{-}\langle \text{identifier} \rangle = rpcb2.s\text{-}\langle \text{identifier} \rangle \Rightarrow$ 
     $action1 \neq action2$ 
     $\vee \neg isSameNode0(action1, action2)$ 
     $\vee isSameNode0(rpcb1, rpcb2)$ 
endlet // action2
endlet // action1

```

If a remote procedure is a value returning procedure, each action shall contain no more than one  $\langle \text{remote procedure call body} \rangle$  used as an  $\langle \text{expression0} \rangle$  for the same remote.

```

 $\forall (cc \in \langle \text{communication constraints} \rangle: (|\{d \in \langle \text{destination} \rangle: d \text{ in } cc\}| > 1)) \Rightarrow$ 
     $cc.parentAS0 \notin \langle \text{remote procedure call body} \rangle \cup \langle \text{import expression} \rangle$ 

```

In Basic SDL-2010, a  $\langle \text{communication constraints} \rangle$  shall contain at most one **to**  $\langle \text{destination} \rangle$  clause. See clause 11.13.4 *Concrete grammar* of [ITU-T Z.101].

Comprehensive SDL-2010  $\langle \text{communication constraints} \rangle$  of an  $\langle \text{output body} \rangle$  of an  $\langle \text{output area} \rangle$  is extended to allow more than one **to**  $\langle \text{destination} \rangle$  clause. See clause 11.13.4 *Concrete grammar* of [ITU-T Z.103].

NOTE 1 – The rule in [ITU-T Z.101] is only extended in [ITU-T Z.103] for  $\langle \text{output body} \rangle$ , therefore a  $\langle \text{communication constraints} \rangle$  in a  $\langle \text{remote procedure call body} \rangle$  or  $\langle \text{import expression} \rangle$  shall contain no more than one  $\langle \text{destination} \rangle$ .

```

 $\forall tc \in \langle \text{timer communication constraint} \rangle: tc.parentAS0.parentAS0 \notin \langle \text{output body} \rangle$ 

```

The  $\langle \text{communication constraints} \rangle$  in an  $\langle \text{output body} \rangle$  shall not contain a  $\langle \text{timer communication constraint} \rangle$ . See clause 11.13.4 *Concrete grammar* of [ITU-T Z.102].

```

 $\forall (tc \in \langle \text{timer communication constraint} \rangle: (|\{tc \text{ in } tc.parentAS0\}| \leq 1)) \Rightarrow$ 
     $tc.parentAS0.parentAS0 \notin (\langle \text{remote procedure call body} \rangle \cup \langle \text{import expression} \rangle):$ 

```

A  $\langle \text{communication constraints} \rangle$  in a  $\langle \text{remote procedure call body} \rangle$  shall contain no more than one  $\langle \text{timer communication constraint} \rangle$ . A  $\langle \text{communication constraints} \rangle$  in an  $\langle \text{import expression} \rangle$  shall contain no more than one  $\langle \text{timer communication constraint} \rangle$ . See clause 11.13.4 *Concrete grammar* of [ITU-T Z.102].

```

 $\forall cc \in \langle \text{communication constraints} \rangle: (cc.s\text{-}\langle \text{destination} \rangle.s\text{-all} \neq \text{undefined}) \Rightarrow$ 
     $(cc.parentAS0 \notin \langle \text{remote procedure call body} \rangle \cup \langle \text{import expression} \rangle)$ 

```

A  $\langle \text{destination} \rangle$  of a  $\langle \text{communication constraints} \rangle$  in  $\langle \text{remote procedure call body} \rangle$  shall not contain **a11**. A  $\langle \text{destination} \rangle$  of a  $\langle \text{communication constraints} \rangle$  in  $\langle \text{import expression} \rangle$  shall not contain **a11**. See clause 11.13.4 *Concrete grammar* of [ITU-T Z.102].

```

 $\forall v \text{ in } \langle \text{timer communication constraint} \rangle.s\text{-}\langle \text{variable} \rangle\text{-seq: } \neg(isGlobalBlockVar0(v))$ 

```

A  $\langle \text{variable} \rangle$  of a  $\langle \text{timer communication constraint} \rangle$  shall not be a global variable of a system (type) or block (type) except if the  $\langle \text{timer communication constraint} \rangle$  is within the state machine actions of system (type) or block (type). See clause 10.5 *Model* of [ITU-T Z.102].

## Transformations

A remote procedure call body

```

– Proc(apar) to destination timer timerinfo via viapath

```

is modelled by an exchange of implicitly defined signals. If the **to** or **via** clauses are omitted from the remote procedure call, they are also omitted in the following transformations. The communication uses the channels where the remote procedure has been mentioned in the  $\langle \text{signal list} \rangle$  (the outgoing for the importer and the incoming for the exporter) of at least one gate or channel connected to the importer or exporter. The requesting agent sends a signal containing the actual parameters of the procedure call, except actual parameters corresponding to **out**-parameters, to the server agent and waits for the reply. In response to this signal, the server agent interprets the corresponding remote

procedure, sends a signal back to the requesting agent with the results of all **in**/**out**-parameters and **out**-parameters (**in** parameters are excluded), and then interprets the transition for the remote procedure stimulus in the current state.

*rp.d.implicitName*

**provided**

```

    rp.d ∈ <remote procedure definition>
  ∧ rp.d.implicitName = undefined
=17=>
  ( implicitName\{( rp.d, undefined )} )
  ∪ { ( rp.d, newName +
    if substring(rp.d.s-<name>, 1, 5) = "#set_"
    then "#" + substring(rp.d.s-<name>, 6, rp.d.s-<name>.length-5) // #varname suffix
      + "#set" // set suffix – indicating remote procedure name starting "#set_" - see F2.2.5.1.3
    elseif substring(rp.d.s-<name>, 1, 5) = "#get_"
    then "#" + substring(rp.d.s-<name>, 6, rp.d.s-<name>.length-5) // #varname suffix
      + "#get" // set suffix – indicating remote procedure name starting "#set_" - see F2.2.5.1.3
    else "" // empty string – not #set or # get
    endif
  ) }

```

*rp.d*=<remote procedure definition>(\*, *sign*)

**provided**

```

    rp.d.implicitName ≠ undefined
=17=>
let p = rp.d.implicitName.s-TOKEN
let sortlist = sign.s-<formal parameter>-seq in
  < rp.d, mk-<signal definition list>(undefined,
    < mk-<signal definition>(
      undefined, // type preamble
      mk-<name >(p+"CALL"), // signal name
      empty, // formal context parameters
      undefined, // specialization
      undefined, // virtuality constraint
      < mk-<sort list>(
        < sortlist[n].s-<sort> | n in 1..sortlist.length : sortlist[n].s-implicit ≠ out > ^
        < predefinedId0("Integer") > ) ), // end mk sort list, end mk signal definition
      < mk-<signal definition>(
        undefined, // type preamble
        mk-<name >(p+"REPLY"), // signal name
        empty, // formal context parameters
        undefined, // specialization
        undefined, // virtuality constraint
        < mk-<sort list>(
          < sortlist[n].s-<sort> | n in 1..sortlist.length :
            (sortlist[n].s-implicit ≠ in ∧ sortlist[n].s-implicit ≠ undefined) > ^
          if sign.s-<result> ≠ undefined then < sign.s-<result> >
          else empty
          endif ^
          < predefinedId0("Integer") > ) ) // end mk sort list, end mk signal definition
        > ) > // end mk signal definition list, end of replacement list
      > ) > // end mk sortlist
endlet // sortlist
endlet // p

```

There are two anonymously named implicit <signal definition list> items for each <remote procedure definition> in a system definition. The <signal name> items in these <signal definition> items are denoted by *pCALL* and *pREPLY* respectively, where *p* is uniquely determined. The signals are defined in the same scope unit as the <remote procedure definition>. Both *pCALL* and *pREPLY* have a last parameter of the predefined *Integer* sort.

< <channel definition>( *n*, *er*, *delay*,

```

    <channel path>(ep1, ep2,
        sigs1 ^ <signal list item>(i=<identifier>(q, *)) ^ sigs2),
    path2) >
provided stimulusKind(i) = remote procedure ^ i.refersto0.implicitName ≠ undefined
=17=>
let p = i.refersto0.implicitName.s-TOKEN in
    mk-<channel definition>(n, er, delay,
        mk-<channel path>(ep1, ep2,
            sigs1 ^ < mk-<signal list item>( <identifier>(q, mk-<name>(p + "CALL")) ) ^ sigs2),
            mk-<channel path>(ep2, ep1,
                if path2 = undefined then empty else path2.s-<signal list item>-seq endif ^
                < mk-<signal list item>( <identifier>(q, mk-<name>(p + "REPLY")) ) > )))
endlet // p

```

On each channel mentioning the remote procedure, the remote procedure is replaced by `pCALL`. For each such channel, if it is unidirectional the channel is made bidirectional. In the opposite direction this channel carries the signal `pREPLY`. The new channel has the same delaying property as the original one.

The transform below replaces an exported procedure definition without an `as` clause by an exported procedure definition with an `as` clause that identifies the remote procedure with the same name as the exported procedure definition.

```

ipd = <internal procedure definition>
provided
    ipd.s-<procedure heading>.s-<procedure preamble>.s-<exported> ≠ undefined
^ ipd.s-<procedure heading>.s-<procedure preamble>.s-<exported>.s-<identifier> = undefined
// exported procedure without an as clause – change to identify remote procedure
=17=>
mk-<internal procedure definition>(
    ipd.s-<package use clause>-seq,
    mk-<procedure heading>(
        mk-<procedure preamble>(
            ipd.s-<procedure heading>.s-<procedure preamble>.s-implicit // virt/abstract,
            mk-<exported>(
                resolveByContainer0(ipd.surroundingScopeUnit0,
                    mk-<identifier>(empty, ipd.s-<procedure heading>.s-<name>),
                    remote procedure).identifier0 // id for rpd
            ) // end mk exported
        ), // end of procedure preamble
        ipd.s-<procedure heading>.s-<qualifier>,
        ipd.s-<procedure heading>.s-<name>,
        ipd.s-<procedure heading>.s-<formal context parameters>,
        ipd.s-<procedure heading>.s-<virtuality constraint>,
        ipd.s-<procedure heading>.s-<specialization>,
        ipd.s-<procedure heading>.s-<procedure formal parameters>,
        ipd.s-<procedure heading>.s-<procedure result>
    ), // end of procedure heading
    ipd.s-<entity in procedure>-seq,
    ipd.s-implicit // body, statements or compound statement
) // end mk internal procedure definition

```

The transform below inserts the implicit variable definitions needed for an exported procedure after an exported procedure definition that has an `as` clause that identifies the remote procedure definition.

```

< ipd = <internal procedure definition> >
provided
    ipd.s-<procedure heading>.s-<procedure preamble>.s-<exported> ≠ undefined
^ ipd.s-<procedure heading>.s-<procedure preamble>.s-<exported>.s-<identifier> ≠ undefined
// exported procedure without an as clause – change to identify remote procedure
^ ¬(∃ v ∈ <variables of sort> :
    v.s-<name> =

```

```

    mk-<name>(ipd.s-<procedure heading>.s-<procedure preamble>
      .s-<exported>.s-<identifier>.refersto0.implicitName.s-TOKEN+"n")
    ^ (fullQualifier0(v) = fullQualifier0(ipd))
    // There is not already a variable with the name p+"n" in the scope ipd defined,
    // where p is the unique name associated with remote procedure definition,
    // therefore the variables need to be defined.
=17=>
let rpd = ipd.s-<procedure heading>.s-<procedure preamble>.s-<exported>.s-<identifier> in
// remote procedure definition id
let p = rpd.refersto0.implicitName.s-TOKEN in
// p is the unique TOKEN associated with remote procedure definition
< ipd > ^
< variableDefinition0(p + "n", predefinedId0("Integer"), undefined) > ^
< variableDefinition0(p + "ivar", predefinedId0("Pid"), undefined) > ^
if rpd.s-<procedure signature>.s-<result> = undefined then
  empty
else
  < variableDefinition0(p + "res", rpd.s-<procedure signature>.s-<result>, undefined) >
endif ,
  remoteProcParamsDef(ipd.s-<procedure heading>.s-<procedure formal parameters>, p)
> // end of replacement
endlet // p
endlet // rpd

```

#### a) Requesting agent

The remote procedure in a requesting agent has seven transforms. The first transform handles the variable definitions for implicit variables and is invoked only once. The subsequent six transforms insert actions before the action containing the remote procedure call body for the signal exchange. Depending on where the remote procedure call was, the pattern matches one of the six transformations for the enclosing body: an agent body with the remote procedure call in a start, an agent body with the remote procedure call in a state or free action, a composite state body with the remote procedure call in a start, a composite state body with the remote procedure call in a state or free action, a procedure body with the remote procedure call in a start, or a procedure body with the remote procedure call in a state or free action. These are invoked only if the implicit variables are defined. If the procedure is in an expression, the remote procedure call is replaced with an access to the implicit variable for the returned value - otherwise the remote procedure call is removed.

```

items= getEntities0(//entities defined in agent type definition where remote procedure is called
  atd = parentAS0ofKind( // finds agent type definition with import expression
    rpcb = <remote procedure call body>,
    <system type definition> ∪ <block type definition> ∪ <process type definition>))
)) //end parentAS0ofKind, end of getEntities0
provided
¬ callerVariablesDefined(rpcb)
=17=>
< variableDefinition0(rpcb.s-<identifier>.refersto0.implicitName.s-TOKEN + "n",
  predefinedId0("Integer"),
  mk-<operand5>( mk-<identifier>( predefinedQual0("Integer"), mk-<name>("1")))) >
^
< variableDefinition0( rpcb.s-<identifier>.refersto0.implicitName.s-TOKEN + "newn",
  predefinedId0("Integer"), undefined) >
^ if rpd.s-<procedure signature>.s-<result> = undefined then empty
else
  < variableDefinition0( rpcb.s-<identifier>.refersto0.implicitName.s-TOKEN + "res",
    rpd.s-<procedure signature>.s-<result>,undefined) >
endif // rpcb is in an expression
^ items // variables are in scope and can be used in items

```

- For each imported procedure, two implicit anonymous `Integer` variables (in this description called `n` and `newn`) are defined in the enclosing scope unit of the `<remote procedure call body>`, and `n` is initialized to 0.

NOTE 2 – The parameter `n` is introduced to recognize and discard reply signals of remote procedure calls that were left through associated timer expiry.

- If remote procedure is a value returning procedure, an implicit anonymous variable (in this description called `res`) is defined in the enclosing scope unit of the `<remote procedure call body>` with the sort returned by the procedure.

```

endlet // actions1

```

- The <remote procedure call body> is transformed as below, so that the following is inserted before the action that contained the <remote procedure call body>, where in the output the **to** clause is omitted if the destination is not present, and the **via** clause is omitted if it is not present in the original expression:

- where  $a_{par}$  is the list of actual parameters except actual parameters corresponding to **out**-parameters, and  $a_{INOUTpar}$  is the modified list of actual **in/out**-parameters and **out**-parameters, including the implicit variable `res` as an additional parameter if a value returning remote procedure call is transformed.
- The transform is labelled with the label on the action containing the remote procedure call or a new label if this action is not labelled, and the preceding path is changed to join this label.
- If a value returning remote procedure call is transformed, the true path above is terminated with a join to the action that contained the remote procedure call with a new label, and the remote procedure call is replaced by an access of the implicit variable `res` used to receive the returned value. Otherwise the remote procedure call action is removed and the true path above is joined to the action following the remote procedure call action.
- Additionally, the following will be inserted if a <timer communication constraint> is included in <communication constraints>

where:

- $t$  is the <timer identifier> in the <timer communication constraint>;
- $a_{params}$  is the optional list of optional <variable> items given after the <timer identifier> in the <timer communication constraint>;

- `tconnect` is the <connector name> if one is given in the <timer communication constraint>; otherwise `tconnect` is the name of the timer.
  - In all other states, `pREPLY` is discarded. This is not explicitly modelled: instead the handling of `pREPLY` is left unspecified in the transformed concrete syntax except for the `pWAIT` states with the consequence that there is an implicit transition (see clause 11.8 of [ITU-T Z.103]) for other states that discards the signal.
  - If the <remote procedure call body> was directly enclosed by a <remote procedure call>, it is an <action> that is the <remote procedure call> and the transform replaces the <remote procedure call body>. Otherwise the <remote procedure call body> is a <value returning procedure call> as an <expression0>, and transform is inserted before the action that contained the <value returning procedure call>, and the <value returning procedure call> is replaced in this action by an access of the implicit variable `res` used to receive the returned value.
- b) Server agent

The ASM for transformations for server agents is given in 3 parts: <input part> where the remote procedure is given explicitly; any <save> where a remote procedure is given explicitly; states in agents that can receive the remote procedure call where the remote procedure is not given explicitly either in an <input part> or a <save part>.

```

**endlet // p**  
**endlet // rpc**

In the server agent, an implicit anonymous Integer variable (in this description called *n*) is defined for each <input> that is a remote-procedure input. Furthermore, there is an implicit anonymous *pid* variable (in this description called *ivar*) for each such <input> defined in the scope where the remote procedure input occurs. If a value returning remote procedure call is transformed, an implicit anonymous variable (in this description called *res*) with the same sort as <sort> in <procedure result> is defined.

- To all <state> items with a remote procedure input transition, the following <input> replaces the remote procedure input and leads to the transition for the remote procedure:

- if a value returning remote procedure call was transformed.
- To all <state> items with a remote procedure save, the following <save> is added:

- To all other <state> items (excluding implicit states derived from input with *pCALL*) where the remote procedure is not shown, the <input> described above is added and terminates in a next state that returns to the same state.

NOTE 3 – There is a possibility of deadlock using the remote procedure construct, especially if no <destination> is given, or if <destination> does not denote a <pid expression> of an agent which is guaranteed

by the specification to exist at the time of receiving the `pCALL` signal. Associated timers allow the deadlock to be avoided.

## Auxiliary functions

The function *implicitName* is used to store the implicitly generated name for a remote entity definition.

```
controlled implicitName: <remote procedure definition> ∪ <remote variable definition> → <name>
initially ∇ r ∈ <remote procedure definition> ∪ <remote variable definition>: r.implicitName = undefined
```

The function *callerVariablesDefined* checks if AS0 has already been modified to include variable definitions in the agent type surrounding the remote procedure call or remote variable import.

```
callerVariablesDefined(rem: <remote procedure call body> ∪ <import expression>): BOOLEAN =def
  rem.s-<identifier>.refersto0.implicitName ≠ undefined
∧ (∃ v ∈ <variables of sort> :
  v.s-<name>.s-TOKEN =
    (rem.s-<identifier>.refersto0.implicitName.s-TOKEN + "n")
  ∧ (fullQualifier0(v) = fullQualifierWithin0(parentAS0ofKind(rem,
    <system type definition> ∪ <block type definition> ∪ <process type definition>)))
  // There is already a variable with the name z + "n" in the type definition surrounding rem
  // where z is the TOKEN for the unique name associated with the remote definition
  // (that is, z = rem.s-<identifier>.refersto0.implicitName.s-TOKEN).
```

The function *variableDefinition0* makes an AS0 <variable definition> for a variable with a <name> that has the given *TOKEN* value, the given <sort> and the given <operand5> constant expression, which should be *undefined* if the variable is not initialized.

```
variableDefinition0(token: TOKEN, sort: <sort>, const: <operand5>): <variable definition> =def
mk-<variable definition>( < mk-<variables of sort>( PART, < mk-<name>( token ) >, sort, const ) > )
```

The function *newActionsIAS0* makes an AS0 <transition action items> or <terminator> to replace the actions before the action containing the remote procedure call.

```
newActionsIAS0(actionsI: <action>*, oldlabel: <name>): <transition action items> ∪ <terminator> =def
if actionsI = empty
then mk-<terminator>( mk-<join>( oldLabel ) )
else mk-<transition action items>( actionsI, mk-<terminator>( mk-<join>( oldLabel ) ) )
endif
```

The function *transformItems0* is used to define a list with a <free action> and a <state> to insert before the action that had the remote procedure call body in the body of an agent, state or procedure.

```
transformItems0(oldlabel: <name>, newlabel: <name>, rpcb: <remote procedure call body>):
  (<state> ∪ <free action>)* =def
let sq = fullQualifierWithin0(parentAS0ofKind(rpcb,
  <system type definition> ∪ <block type definition> ∪ <process type definition>)) in

> // for other states nothing is specified for p + "REPLY" so it is treated as an implicit transition
endlet // pWAIT
endlet // pREPLY
endlet // pCALL
endlet // p
endlet // resid
endlet // newn
endlet // n
endlet // nid
endlet // rpc
endlet // sq

```

The function *newActions2AS0* makes an AS0 <transition action items> or <terminator> to replace the actions after the action containing the remote procedure call. If the remote procedure call is in an expression, the action containing the remote procedure call has the call changed to access the implicit variable to the result of the call. Otherwise, the action is the remote procedure call and is removed.

```

newActions2AS0( actions2: <action>*, newlabel: <name>, rpcb: <remote procedure call body>,
  tr: <terminator>): (<state> ∪ <free action>)* =def
let sq = fullQualifierWithin0( parentAS0ofKind( rpcb,
  <system type definition> ∪ <block type definition> ∪ <process type definition>)) in
< mk-<free action>(
  mk-<transition action items>(
    if rpcb.parentAS0 ∉ <remote procedure call>

```

```

then // <remote procedure call body> in <expression>
  < mk-<action>(newLabel,
    replaceOnceInSyntaxTree0(rpcb,
      mk-<operand5>(mk-<variable access>(mk-<identifier>(
        sq, mk-<name>( rpcb.s-<identifier>.refersto0.implicitName.s-TOKEN + "res")))),
      parentAS0ofKind(rpcb, <action>).s-implicit) // replace rpcb by res access in action
    > ^ actions2
  else // <remote procedure call body> in <remote procedure call> -
    if actions2 ≠ empty
      then < mk-<action>(newLabel, actions2.head.s-implicit) > ^ actions2.tail
    else // dummy action n := n+0 so action can be labelled!
      < mk-<action>( newLabel, mk-<task>( mk-<assignment>(
        mk-<identifier>(sq, rpcb.s-<identifier>.refersto0.implicitName.s-TOKEN + "n"),
        mk-<operand5>(mk-<variable access>(mk-<identifier>(sq,
          mk-<name>(rpcb.s-<identifier>.refersto0.implicitName.s-TOKEN+ "n")))),
        ))) // assignment, task, action
      > // action list
    endif,
  endif,
  tr) //transition action items
) > // free action, sequence
endlet // sq

```

The function *bilistpre0* takes a body list of <state> and <free action> items, and produces a new list where the given item (<state> or <free action>) and all subsequent items are deleted, so that the new list can be used to replace the first part of the body list.

```

bilistpre0(bl:(<state> ∪ <free action>)*, bsf:<state> ∪ <free action>):(<state> ∪ <free action>)* =def
  if bl.length = 1 ∨ bl.tail.head = bsf
  then empty
  else < bl.head > ^ bilistpre0(bl.tail,bsf)
  endif

```

The function *revisedState0* takes <state> item, and returns a new <state> item, where each part of the <state> (<input part>, <priority input>, <save>, <state timer input>) is the result of *revisedStatePart0* that returns a modified part only for the part that contains the given action.

```

revisedState0(st(statenames, stateparts, statetimer): <state>, action: <action>,
  newactions1: <transition action items> ∪ <terminator>):<state> =def
  st( statenames,
    < revisedStatePart0(stateparts[i], action, newactions1) | i in 1..stateparts.length >,
    revisedStatePart0(statetimer, action, newactions1))

```

The function *revisedStatePart0* takes state part, and returns the same state part if it does not contain (is not a parent of) the given action, otherwise it returns a revised part where the transition containing the action is replaced the given transition parameter.

NOTE 4 – Assuming the original transition containing *action* is of the form *actions1* ^ *action* ^ *actions2* then the replacement *newactions1* is a version of *actions1* that ends with a join to the new actions inserted before the old *action*. The replacement for *action* and the subsequent *actions2* are placed in <state> and <free action> items in the body item list of the body. The order of these items does not really matter as they connected by state names and labels that also ensure that no change is needed to the rest of the revised state and any other state. If *action* was labelled, this label is moved to the start actions inserted before *action*, therefore any join to *action* becomes a join to this point.

```

revisedStatePart0(part: STATEPART0, action: <action>,
  newactions1: <transition action items> ∪ <terminator>): STATEPART0 =def
  let anspart = parentAS0ofKind(action, <textual answer part>) in

  < mk-<variable definition>(
    < <variables of sort>(
      PART,< <name>(p + natToIntToken(fpl.length)) >, fpl.head.s-<sort>, undefined) >
    ) >
    ^ remoteProcParamsDef(fpl.tail, p)
  endif

```

The function *remoteProcParams* produces a list of variable identifiers to hold the values passed via the pCALL signal for a remote procedure call before calling the exported procedure. The *fpl* parameter is the list of formal parameters for the remote procedure and the *vars* parameter is the list of variable definitions in server agent created from the list of formal parameters.

```

remoteProcParams(fpl: <formal parameter>*, vars: <variable definition>*):<identifier>* =def
if fpl.length = 0 then empty
else
  if fpl.head.s-implicit ≠ out then
    < mk-<identifier>(vars.head.fullQualifier0, vars.head.s-<variables of sort>.s-<name>) >
  else empty
  endif
  ^ remoteProcParams(fpl.tail, vars.tail)
endif

```

The function *exportedProcParams* produces a list of variable identifiers to use in the call of the exported procedure after the input of *pCALL*. The *fpl* parameter is the list of formal parameters for the remote procedure and the *vars* parameter is the list of variable definitions in server agent created from the list of formal parameters.

```

exportedProcParams(fpl: <formal parameter>*, vars: <variable definition>*):<identifier>* =def
if fpl.length = 0 then empty
else
  < mk-<identifier>(vars.head.fullQualifier0, vars.head.s-<variables of sort>.s-<name>) >
  ^ exportedProcParams(fpl.tail, vars.tail)
endif

```

The function *aINOUTremoteProcParams* produces variable identifier list for the values passed via the *pREPLY* signal of a remote procedure call with the list being in the order of each IN/OUT or OUT parameter.

```

aINOUTremoteProcParams(fpl: <formal parameter>*, vars: <variable definition>*):<identifier>* =def
if fpl.length = 0 then empty
else
  if fpl.head.s-implicit ≠ in ∧ fpl.head.s-implicit ≠ undefined then
    < mk-<identifier>(vars.head.fullQualifier0, vars.head.s-<variables of sort>.s-<name>) >
  else empty
  endif
  ^ aINOUTremoteProcParams(fpl.tail, vars.tail)
endif

```

### F2.2.7.6 Remote variable

NOTE 1 – A remote variable enables an exported value of a variable owned by one agent (the exporter) to be imported into another agent (the importer) by using an <import expression>, and because a remote variable is allowed to be used by more than one exporter, it is allowed to direct the request for the exported value to be to a particular agent (or agent instance set) by the <destination> in the <communications constraint> of the <import expression>. In the transform (described below) the <output> request includes the <destination> of the <import expression>, and output compatibility (that the signal is receivable by the destination) applies for the request. If the <destination> is a <pid-expression> with a pid sort (the sort of an *Interface-definition*) other than *Pid*, ASI is statically checked for output compatibility. If the sort is *Pid*, output compatibility needs to be checked dynamically.

#### Concrete syntax

```

<remote variable definition> :: <remote variables of sort>+
<remote variables of sort> ::
  <remote variable<name>+ <sort> [ nodelay ]
<export statement> :: <export body>
<export body> :: <variable<identifier>+

```

#### Conditions on concrete syntax

See clause 10.6 *Model* of [ITU-T Z.102] unless another reference is given.

```

∀v ∈ <exported variables of sort>: ∀ev in v.s-<exported variable>-seq:
  ev.s-<identifier> ≠ undefined ⇒
    isSameSort0(ev.parentAS0.s-<sort>, getEntityDefinition0(ev.s-<identifier>, remote variable).s-<sort>)

```

The <remote variable identifier> following **as** in an exported variable definition shall denote a <remote variable definition> of the same sort as the exported variable definition.

```

∀v ∈ <exported variables of sort>: ∀ev in v.s-<exported variable>-seq:
  let rvd = resolveByContainer0(ev.surroundingScopeUnit0,
    mk-<identifier>(empty, ev.s-<name>),
    remote variable)

```

```

in
   $rvd \neq \text{undefined} \wedge ev.s\text{-}\langle \text{identifier} \rangle = \text{undefined} \Rightarrow$ 
   $isSameSort0(ev.parentAS0.s\text{-}\langle \text{sort} \rangle, rvd.s\text{-}\langle \text{sort} \rangle)$ 
endlet

```

In the case of no **as** clause, the remote variable definition in the nearest enclosing scope unit with the same name and sort as the exported variable definition is denoted.

$$\forall vid \in \langle \text{identifier} \rangle: vid.parentAS0 \in \langle \text{export body} \rangle \Rightarrow getEntityDefinition0(vid, \mathbf{variable}).isExported0$$

The  $\langle \text{variable identifier} \rangle$  in  $\langle \text{export statement} \rangle$  shall denote a variable defined with **exported**.

```

 $\forall dest \in \langle \text{identifier} \rangle \cup \mathbf{this}: \forall importExp \in \langle \text{import expression} \rangle:$ 
   $dest.parentAS0 = importExp \Rightarrow$ 
  ( let  $def =$ 
    if  $dest \in \langle \text{identifier} \rangle$ 
    then  $getEntityDefinition0(dest, \mathbf{sort})$ 
    else  $getEntityDefinition0($ 
       $parentAS0ofKind(dest, \langle \text{agent definition} \rangle \cup \langle \text{agent type definition} \rangle).s\text{-}\langle \text{identifier} \rangle, \mathbf{sort})$ 
    endif
    in
    let  $rv = getEntityDefinition0(importExp.s\text{-}\langle \text{identifier} \rangle, \mathbf{remote variable})$  in
       $def \in \langle \text{interface definition} \rangle \wedge isDefinedIn0(rv, def)$ 
    endlet
  )
endlet

```

If  $\langle \text{destination} \rangle$  in  $\langle \text{communication constraints} \rangle$  of an  $\langle \text{import expression} \rangle$  is an  $\langle \mathbf{agent} \langle \text{identifier} \rangle \rangle$  or **this**, the  $\langle \text{remote variable identifier} \rangle$  shall represent a remote variable contained in the interface of the agent type.

```

 $\forall v \in \langle \text{exported variables of sort} \rangle:$ 
   $parentAS0ofKind(v, \langle \text{internal procedure definition} \rangle) = \text{undefined}$ 

 $\forall ie1, ie2 \in \langle \text{import expression} \rangle:$ 
let  $action1 = parentAS0ofKind(ie1, \langle \text{action} \rangle)$  in
let  $action2 = parentAS0ofKind(ie2, \langle \text{action} \rangle)$  in
   $ie1.s\text{-}\langle \text{identifier} \rangle = ie2.s\text{-}\langle \text{identifier} \rangle \Rightarrow$ 
     $action1 \neq action2$ 
   $\vee \neg isSameNode0(action1, action2)$ 
   $\vee isSameNode0(ie1, ie2)$ 
endlet
endlet

```

Each action shall contain no more than one  $\langle \text{import expression} \rangle$  for the same remote variable.

A procedure variable is not allowed to be exported (see clause 9.4 *Semantics* of [ITU-T Z.101]). The definition of **exported** variables is not allowed in a  $\langle \text{variable definition} \rangle$  in a  $\langle \text{procedure definition} \rangle$  (see clause 9.4 *Concrete grammar* of [ITU-T Z.103]).

## Transformations

The use of  $\langle \text{import expression} \rangle$  in an expression is shorthand for inserting a task just before the action, where the expression occurs which assigns to an implicit variable the result of the  $\langle \text{import expression} \rangle$  and then uses that implicit variable in the expression. If  $\langle \text{import expression} \rangle$  occurs several times in an expression, one variable is used for each occurrence. See clause 12.3.4.5 *Model* of [ITU-T Z.104].

An import access is modelled by exchange of implicitly defined signals. The importer sends a signal to the exporter, and waits for the reply. In response to this signal the exporter sends a signal back to the importer with the result contained in the implicit copy of the exported variable. See clause 10.6 *Model* of [ITU-T Z.102].

$$rvd.implicitName$$

```

provided
  rvd ∈ <remote variable definition>
  ∧ rvd.implicitName = undefined
=17=>
(implicitName\{( rvd, undefined )} ) ∪ {( rvd, newName)}

rvd=<remote variable definition>( <remote variables of sort>( <n >, sort, delay ) >)
provided
  rvd.implicitName ≠ undefined // implicit name defined
  ∧ ¬ (∃ sigdef ∈ <signal definition>: sigdef.s-<name>.s-TOKEN = rvd.implicitName.s-TOKEN + "QUERY")
  // signal xQUERY already defined for this remote variable
=17=>
let x = rvd.implicitName.s-TOKEN in
  rvd ^ mk-<signal definition list>(
    < mk-<signal definition> (undefined,
      mk-<name>(x + "QUERY"), empty, undefined, undefined, < predefinedId0("Integer") > ) ,
      mk-<signal definition> (undefined,
      mk-<name>(x + "REPLY"), empty, undefined, undefined, < sort, predefinedId0("Integer") > )
    > )
  endlet // x

```

There are two implicit signal definitions for each variable of a <remote variable definition> in a system definition. A <remote variable definition> that defines multiple variables is expanded to a <remote variable definition> list with one variable per <remote variable definition>. The <signal name>s in the implicit signal definitions are denoted by xQUERY and xREPLY respectively, where x denotes an implicit <name> associated with the <remote variable definition>. The signals are defined in the same scope unit as the <remote variable definition>. The signal xQUERY has an argument of the predefined sort Integer and xREPLY has arguments of the sort of the variable and Integer. See clause 10.6 *Model* of [ITU-T Z.102].

```

<channel definition>(n, er, delay,
  <channel path>(ep1, ep2,
    sigs1 ^ <signal list item>(i=<identifier>(q, *)) ^ sigs2),
  path2)
provided
  stimulusKind(i) = remote variable
  ∧ i.refersto0.implicitName ≠ undefined
=17=>
let x = i.refersto0.implicitName.s-TOKEN in
  mk-<channel definition>(n, er, delay,
    mk-<channel path>(ep1, ep2,
      sigs1 ^ < mk-<identifier>(q, mk-<name>(x + "QUERY")) > ^ sigs2),
    mk-<channel path>(ep2, ep1,
      if path2 = undefined then empty else path2.s-<signal list item>-seq endif ^
      < mk-<identifier>(q, mk-<name>x + "REPLY")) >))
  endlet

```

On each channel mentioning the remote variable, the remote variable is replaced by xQUERY. For each such channel, if it is unidirectional the channel is made bidirectional. In the opposite direction this channel carries the signal xREPLY. See clause 10.6 *Model* of [ITU-T Z.102].

#### a) Importer

See clause 10.6 *Model* (a) Importer of [ITU-T Z.102].

The first transformation below inserts variable definitions for the implicit variables needed for an import expression provided a unique name associated with the remote variable has been introduced and the variables have not already been defined. The second transformation updates the access of the remote variable to be an access of the implicit variable used to store the import value from the signal exchange for the import, and is followed by dependent transformations one of which inserts the items for the signal exchange before the variable access. Depending on where the import expression was,

the pattern matches one of the six dependent transformations for the enclosing body: an agent body with the import expression in a start, an agent body with the import expression in a state or free action, a composite state body with the import expression in a start, a composite state body with the import expression in a state or free action, a procedure body with the import expression in a start, or a procedure body with the import expression in a state or free action.

```

items=getEntities0(//entities defined in agent type definition where import expression is used
  atd = parentASOfKind( // finds agent type definition with import expression
    r = <import expression>(rv, *),
    <system type definition> ∪ <block type definition> ∪ <process type definition>))
)) //end parentASOfKind, end of getEntities0
provided
¬ callerVariablesDefined(r)
=17=>
< variableDefinition0(rv.refersto0.implicitName.s-TOKEN + "xn", rv.refersto0.s-<sort>, undefined),
  variableDefinition0(rv.refersto0.implicitName.s-TOKEN + "n", predefinedId0("Integer"),

endlet // newLabel
endlet // oldLabel
endlet // actions2
endlet // actions1

```

- For each imported variable, two implicit `Integer` variables (in this description called `n` and `newn`) are defined in the enclosing scope unit of the `<import expression>`, and `n` is initialized to 0. In addition, an implicit anonymous variable (in this description called `xn`) of the sort of the remote variable is defined.

- The `<import expression>`

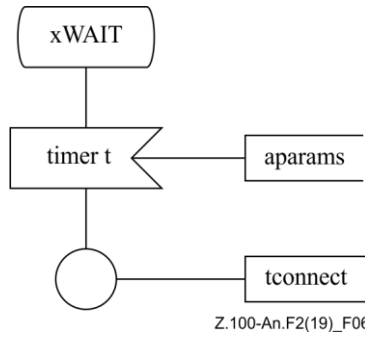

`import (x to destination via via-path)`

is transformed so that the following is inserted before the action that contained the `<import expression>`, where in the output the `to` clause is omitted if the destination is not present, and the `via` clause is omitted if it is not present in the original expression:

Z.100-An.F2(19)\_F05

- The insertion is labelled with the label on the action containing the import expression or a new label if this action is not labelled, and the preceding path is changed to join this label.
- The true path above is terminated with a join to the action that contained the import expression with a new label.
- The import expression is changed to an access of the variable `xn`.
- In all other states, `xREPLY` is discarded. This is not explicitly modelled: instead the handling of `xREPLY` is left unspecified in the transformed concrete syntax except for the `xWAIT` states with the consequence that there is an implicit transition (see clause 11.8 of [ITU-T Z.103]) for other states that discards the signal.
- Additionally, the following is inserted for every timer `t` that is included in `<communication constraints>`:

where:

*t* is the <timer identifier> in the <timer communication constraint>;

*aparams* is the optional list of optional <variable> items given after the <timer identifier> in the <timer communication constraint>;

*tconnect* is the <connector name> if one is given in the <timer communication constraint>; otherwise *tconnect* is the name of the timer.

b) Exporter

See clause 10.6 *Model* (b) Exporter of [ITU-T Z.102].

The first transform below handles the variable definitions for implicit anonymous variable to store the exported value and the implicit anonymous variable to store the integer passed received in xQUERY and returned in xREPLY. The subsequent three transforms modify the bodies of agents, composite states and procedures (respectively) where an exported variable is in scope to include the xQUERY handler on all states.

```

v = <variable definition>( < <exported variables of sort>( ak, < <exported variable>(*, rv) >, sort), const >)
provided
  rv.refersto0.implicitName ≠ undefined // implicit name defined
  ¬(∃ vos ∈ <variables of sort>: vos.s-<name>-seq[1].s-TOKEN = rv.refersto0.implicitName.s-TOKEN+"imcx"
    ∧ surroundingQualifier0(vos) = surroundingQualifier0(v)) // imcx not defined
=17=>
let imcxName = mk-<name>( rv.refersto0.implicitName.s-TOKEN+"imcx" ) in
v mk-<variable definition>( < mk-<variables of sort>( ak, < imcxName >, sort, const ) >
  variableDefinition0( rv.refersto0.implicitName.s-TOKEN+"n", predefinedId0("Integer"), undefined ) >
endlet

```

For each exported variable, an implicit anonymous variable (in this description denoted by *imcx*) is defined to hold the exported value of the exported variable, and an implicit anonymous variable of type Integer (in this description denoted by *n*) is defined.

If a default initialization is attached to the export variable or if the export variable *imcx* is initialized when it is defined, then the implicit copy is also initialized with the same result as the export variable.

```

body = <agent body>( start, bodyitems )
provided
  ( ∃ ev ∈ <exported variable>: exportedVarScope0(ev, body) )
  //There exists an exported variable ev whose scope encloses the body, with no xQUERY input parts
=17=>
mk-<agent body>( start, newBodyitems0(body) )

```

```

body = <composite state body>( startlist, bodyitems )
provided
  ( ∃ ev ∈ <exported variable>: exportedVarScope0(ev, body) )
  //There exists an exported variable ev whose scope encloses the body, with no xQUERY input parts
=17=>
mk-<composite state body>( startlist, newBodyitems0(body) )

```

*body* = <procedure body>( *start*, *bodyitems*)

**provided**

(  $\exists ev \in$  <exported variable>: *exportedVarScope0*(*ev*, *body*))

//There exists an exported variable *ev* whose scope encloses the body, with no xQUERY input parts  
=17=>

**mk**-<procedure body>( *start*, *newBodyitems0*(*body*))

- To all states of the exporter, the following input is added:

<export statement>( <export body>( <id >))

=17=>

**mk**-<task>( **mk**-<assignment>( *id.refersto0.implicitName*, *id*))

The <export statement>

**export** *x*

is transformed to the following:

**task** *imcx* := *x*;

NOTE 2 – There is a possibility of deadlock using the import construct, especially if no <destination> is given, or if <destination> does not denote a <pid expression> of an agent which is guaranteed by the specification to exist at the time of receiving the xQUERY signal. Specifying a set timer in the <import expression> avoids such a deadlock.

The keyword **nodelay** has no SDL-2010 meaning, though to be compatible with SDL-92 the channel conveying the signals for the remote variable should be a channel without delay.

## Auxiliary functions

The function *newImportItems* is used to define a list of <free action> and <state> items to insert into the body of an agent, state or procedure that has an import expression.

*newImportItems*(*r*: <import expression>, *oldlabel*: <label>, *newlabel*: <label>):

( <free action>  $\cup$  <state>)\* =def

**let** *sq* = *fullQualifierWithin0*( *parentAS0ofKind*( *r*,

<system type definition>  $\cup$  <block type definition>  $\cup$  <process type definition>))

**in**

**let** *rv* = *r.s*-<identifier> **in**

**let** *constr* = *r.s*-<communication constraints> **in**

**let** *xnName* = **mk**-<name>( *rv.refersto0.implicitName.s-TOKEN* + "xn") **in**

**let** *nName* = **mk**-<name>( *rv.refersto0.implicitName.s-TOKEN* + "n") **in**

endlet // xnName
endlet // constr
endlet // rv
endlet // sq

```

The function *exportedVarScope0* determines if there is an agent type definition that has a variable definition where the given exported variable *ev* is defined, and encloses the given body in which there is no input part that handles the *xQUERY* signal for the exported variable.

```

exportedVarScope0(ev: <exported variable>,
  body: <agent body> ∪ <composite state body> ∪ <procedure body>): BOOLEAN =def
// ev.s-<identifier> is remote variable identifier
// <exported variable> is only in <variable definition> which at this point has one variable per definition
ev.s-<identifier>.refersto0.implicitName ≠ undefined // implicit name defined
∧ isSameNode0( // nearest enclosing agent type def of body and ev the same agent type definition
  parentAS0ofKind(body, <system type definition> ∪ <block type definition> ∪ <process type definition>),
  parentAS0ofKind(ev, <system type definition> ∪ <block type definition> ∪ <process type definition>))
∧ ¬ (∃ input ∈ <input part>:
  parentAS0ofKind(input, <agent body> ∪ <composite state body> ∪ <procedure body>) = body
  ∧ parentAS0ofKind(rv.refersto0.implicitName.s-TOKEN + "QUERY", <input part>) = input)
// does not exist an input part in body for xQUERY

```

The function *newBodyItems0* takes a body (an agent body, composite state body or procedure body), and provides a replacement list for the body items of the body where every state has a handler for *xQUERY* added.

```

newBodyItems0(body: <agent body> ∪ <composite state body> ∪ <procedure body>):
  (<state> ∪ <free action>)-seq =def
let bodyitems = body.s-<state> ∪ <free action>-seq in

  er.s3-Identifier = predefinedId1("decode" + "APER") // decode identifier
otherwise
  getEntityDefinition1(er.s2-Identifier, procedure) ≠ undefined
  ∧ er.s2-Identifier.s-Name = "encode" + ri.s-Name
  ∧ getEntityDefinition1(er.s2-Identifier, procedure) ≠ undefined
  ∧ er.s2-Identifier.s-Name = "decode" + ri.s-Name

endcase
endlet // ri

```

The *Rules-identifier* shall be one of the literal identifiers of the data type `Encoding`. The data type `Encoding` shall be the Predefined data type `Encoding` or a data type with the name `Encoding` that is a specialization (direct or indirect) of the Predefined data type `Encoding`. The specialization shall only add literal names to the Predefined data type `Encoding` and shall not change any other properties.

If the *Rules-identifier* corresponds (by *Name*) to an `Encoding` literal defined in the `package` `Predefined`, built-in procedures implied by the standardized sets of encoding rules are invoked (and other procedures – even if visible with names corresponding as below – are ignored). These built-in encode and decode procedures are implicit parts of `package` `Predefined`.

If the *Rules-identifier* corresponds to an additional literal added to a specialization of the predefined data type `Encoding`, there shall be a visible procedure with the appropriate signature for each invocation (implicit or explicit) of the *Encoding-expression* or *Decoding-expression*.

The name of the procedure for encode is the name `encode` concatenated with the name of an `Encoding` literal. This procedure shall have one parameter of the implicit choice type for the relevant path for the invocation. The procedure shall return a `Charstring`, `Bitstring` or `Octetstring`.

The name of the procedure for decode is the name `decode` concatenated with the name of an `Encoding` literal. This procedure shall have one parameter of the same type (`Charstring`, `Bitstring` or `Octetstring`) as the corresponding procedure for encode, and shall return the choice type for the relevant path for the invocation.

```

    ∀ er ∈ Encoding-rules : (
      pd ∈ { getEntityDefinition1(er.s2-Identifier, procedure), getEntityDefinition1(er.s3-Identifier, procedure) }
      ⇒ isFunctional1(pd)
    )

```

Each encode or decode procedure shall be functional (that is, it shall not contain states and shall not change the value of any variable external to the procedure when it is interpreted).

```

    ∀ encExp ∈ Encoding-expression : (
      encExp.s-implicit-seq.length
      = getEntityDefinition1(encExp.s-Signal-identifier, signal).s-Signal-parameter-seq.length
    )

```

The length of the optional *Expression* list of an *Encoding-expression* shall be the same as the number of *Sort-reference-identifiers* in the *Signal-definition* denoted by the *Signal-identifier*.

```

    ∀ encExp ∈ Encoding-expression : ∀ i ∈ { 1..encExp.s-implicit-seq.length } :
    (if encExp.s-implicit-seq[i] ≠ undefined
     then
       isCompatibleTo1(encExp.s-implicit-seq[i].staticSort1,
                       getEntityDefinition1(encExp.s-Signal-identifier,
                                             signal).s-Signal-parameter-seq[i].s-Sort-reference-identifier
                       )
     else true
    endif)

```

Each *Expression* in an *Encoding-expression* shall be sort compatible to the corresponding (by position) *Sort-reference-identifier* in the *Signal-definition* denoted by the *Signal-identifier*.

```

    gi ∈ Gate-identifier ∧ gi.parentAS1 ∈ Encoding-path ∧ gi.parentAS1.parentAS1 ∈ Encoding-expression ⇒
    ( (getEntityDefinition1(gi, gate) // gate is gate of the agent (type)
      ∈ parentAS1ofKind(gi.parentAS1.parentAS1, Agent-type-definition).s-Gate-definition-set)
    )
    ∧ // out signal identifier set of the gate includes the signal
    ( gi.parentAS1.parentAS.s-Signal-identifier ∈ getEntityDefinition1(gi, gate).s-Out-signal-identifier-set )

```

For a *Gate-identifier* of an *Encoding-path* of an agent's *Encoding-expression*, the gate shall be a gate of the agent, and the *Out-signal-identifier-set* of the gate shall include the *Signal-identifier*.

```

    dti ∈ Data-type-identifier ∧ dti.parentAS1 ∈ Encoding-path
    ⇒ getEntityDefinition1(dti, sort) ∈ Interface-definition

```

The *Data-type-identifier* of an *Encoding-path* shall identify an *Interface-definition*.

```

    dti ∈ Data-type-identifier
    ∧ dti.parentAS1 ∈ Encoding-path
    ∧ dti.parentAS1.parentAS1 ∈ Encoding-expression
    ⇒ dti.parentAS1.parentAS.s-Signal-identifier ∈ getEntityDefinition1(dti, sort).s-Signal-identifier-set

```

For an *Encoding-path* of an *Encoding-expression* with a *Data-type-identifier* that identifies an *Interface-definition*, the *Signal-identifier* shall identify one of the signals defined or inherited by the interface identified.

```

expr ∈ Expression ∧ expr.parentAS1 ∈ Decoding-expression
let er =
if Decoding-expression.s-Encoding-path ∈ Gate-identifier
then getEntityDefinition1(Decoding-expression.s-Encoding-path.s-Gate-identifier, gate).s-Encoding-rules
else Decoding-expression.s-Encoding-path.s-Encoding-rules
endif
in
⇒
isCompatibleTo1(expr.staticSort1,
   getEntityDefinition1(er.s-Encode-procedure-identifier, procedure).s-Result)
endlet // er

```

The *Expression* in a *Decoding-expression* shall be compatible with the sort generated by an *Encoding-expression* using the same *Encoding-path*.

## Concrete syntax

      then <sigdef.identifier0: sigdef ∈ encodedgt.s-<identifier>.referto0.definedSignalSet0 >
      else empty
      endif
    endif
}) // the unique path that satisfies the condition
endlet // eecontext
) // encoding expression

```

The <encoding path> shall only be omitted from <encoding expression> if there is exactly one path (channel or gate) with encoding for output (of the signal if a <signal identifier> is given) in the context of the <encoding expression>. See clause 10.7 *Concrete grammar* of [ITU-T Z.104].

If <encoding path> is omitted from <encoding expression>, the unique path required by the condition in the *Concrete grammar* is inserted. See clause 10.7 *Model* of [ITU-T Z.104].

```

de = <decoding expression>( expr, undefined )
=8=>
mk-<decoding expression>( expr,
let decontext = parentAS0ofKind(de, // context of encoding expression
  <block definition> ∪ <block type definition>
  ∪ <composite state definition> ∪ <composite state type definition>

```

```

    ∪ <process definition> ∪ <process type definition>
    ∪ <system type definition> ) in
if decontext ∈ (<block definition> ∪ <composite state definition> ∪ <process definition>) then
take({ encodedch: encodedch ∈ <channel definition>
    ∧ encodedch.s-<encoding rules> ≠ undefined // has encoding rules
    ∧ encodedch.s1-<channel path>.s2-<channel endpoint>.refersto0 = decontext // to agent/state
    }) // the unique path that satisfies the condition
else // block, composite state, process or system type
take{ encodedgt: encodedgt ∈ (<textual gate definition> ∪ <textual interface gate definition> )
    ∧ encodedgt.s-<encoding rules> ≠ undefined
    ∧ parentAS0ofKind(encodedgt, <block type definition> // context of encoding expression
    ∪ <composite state type definition> ∪ <process type definition> ∪ <system type definition> )
    = decontext // gate defined in type that is context of de
    }) // the unique path that satisfies the condition
endlet // decontext

```

The <encoding path> shall only be omitted from <decoding expression> if there is exactly one path (channel or gate) with encoding for input in the context of the decoding expression. See clause 10.7 *Concrete grammar* of [ITU-T Z.104].

If <encoding path> is omitted from <decoding expression>, the unique path required by the condition in the *Concrete grammar* is inserted. See clause 10.7 *Model* of [ITU-T Z.104].

```

ep = <encoding path>( chid )
provided chid.refersto0 ∈ <channel definition>
∧ ep.parentAS0 ∈ (<encoding expression> ∪ <decoding expression>) // not <input list> case
∧ ep.surroundingScopeUnit0 ∈ <composite state type definition>
// agent definition and agent type definition transformed, therefore ep is in a composite state type defn.
=12=>
let fwdpathfrom = chid.refersto0.s1-<channel path>.s1-<channel endpoint> in
let fwdpathto = chid.refersto0.s1-<channel path>.s2-<channel endpoint> in
mk-<encoding path>-(
    take(
        { gid :
            gid.refersto0 ∈ <textual gate definition> // interface gate definitions have been transformed
            ∧
            ( // consider both ends of channel
                ( // from endpoint for channel
                    fwdpathfrom.s-implicit ∈ <identifier>
                    ∧ fwdpathfrom.s-implicit.refersto0 ∈ <typebased composite state>
                    ∧ fwdpathfrom.s-implicit.refersto0.s-<type expression>.s-<identifier>.refersto0
                    = ep.surroundingScopeUnit0
                    // state id in from fwd path refers to typebased cs based on state type
                    ∧ fwdpathfrom.s-<name> = gid.s-<name> // names match so same gate
                ) // from endpoint for channel
                ∨
                ( // to endpoint for channel
                    fwdpathto.s-implicit ∈ <identifier>
                    ∧ fwdpathto.s-implicit.refersto0 ∈ <typebased composite state>
                    ∧ fwdpathto.s-implicit.refersto0.s-<type expression>.s-<identifier>.refersto0
                    = ep.surroundingScopeUnit0
                    // state id in to fwd path refers to typebased cs based on state type
                    ∧ fwdpathto.s-<name> = gid.s-<name> // names match so same gate
                ) // to endpoint for channel
            ) // consider both ends of channel
        } //gid set – should be just one gate identifier in the set
    ) // take
) // encoding path
endlet // fwdpathto
endlet // fwdpathfrom

```

If an <encoding path> contains a <channel<identifier>, this is transformed to the (possibly anonymous) <gate<identifier> for the gate of the identified channel nearest to the agent containing the <encoding path>.

## Mapping to abstract syntax

```

| er=<encoding rules>(ri) then
  mk-Encoding-rules(Mapping(ri),
    case ri.s-<name> of // name of rules identifier
    | { "text",
        "BER", "CER", "DER", "APER", "UPER", "CAPER",
        "CUPER", "BXER", "CXER", "EXER", "OER" }
        then predefinedIdI("encode" + ri.s-<name>)
    | "PER" then predefinedIdI("encode" + "APER")
    otherwise
      Mapping(resolveByContainer0(er.surroundingScopeUnit0,
        mk-<identifier>(undefined, mk-<name>("encode" + ri.s-<name>)),
        procedure).identifier0)
    endcase,
    case ri.s-<name> of // name of rules identifier
    | { "text",
        "BER", "CER", "DER", "APER", "UPER", "CAPER",

    mk-Encoding-path(Mapping(ep.s-implicit.s1-<identifier>)),
    mk-Encoding-rules(Mapping(ep.s-implicit.s2-<identifier>))
  endif

| <decoding expression>(expr, ep) then
  mk-Decoding-expression(Mapping(expr), Mapping(ep))

```

## F2.2.8 Behaviour

### F2.2.8.1 Start

#### Abstract syntax

*State-start-node* :: *Transition*  
*Procedure-start-node* :: *Transition*

#### Concrete syntax

<start> :: [<virtuality>] [<state entry point<name>] <transition>

#### Conditions on concrete syntax

∀ *s* ∈ <start>:  
 (*s.s*-<name> ≠ undefined) ⇒

(*s.surroundingScopeUnit0* ∈ <composite state definition>) ∨  
(*s.surroundingScopeUnit0* ∈ <composite state type definition>)

If <state entry point name> is given in a <start>, the <start> shall be the <start> of a composite state. See clause 11.1 *Concrete grammar* of [ITU-T Z.102].

NOTE – A <composite state definition> is transformed into a typebased composite state and a <composite state type definition>.

## Mapping to abstract syntax

```
| s = <start>(*, entry, trans) then
  if s.parentAS0 ∈ <procedure body>
  then mk-Procedure-start-node(Mapping(trans))
  elseif entry = undefined
  then mk-State-start-node(Mapping(trans))
  else mk-Named-start-node(Mapping(entry), Mapping(trans))
endif
```

### F2.2.8.2 State

#### Abstract syntax

<i>State-node</i>	::	<i>State-name</i> <i>Save-signalset</i> <i>Input-node-set</i> { <i>Spontaneous-transition-set</i> <i>Continuous-signal-set</i>   <i>Composite-state-type-identifier</i> <i>Connect-node-set</i> } [ <i>State-timer</i> ]
<i>State-timer</i>	::	<i>Time-expression</i> <i>Timer-identifier</i> <i>Expression</i> * <i>Transition</i>

#### Conditions on abstract syntax

$\forall sn, sn1 \in \text{State-node}: (sn \neq sn1) \wedge (sn.\text{parentAS1} = sn1.\text{parentAS1}) \Rightarrow (sn.s\text{-Name} \neq sn1.s\text{-Name})$

Each *State-node* within a graph (*State-transition-graph* or *Procedure-graph*) shall have a *State-name* different from any other *State-name* in the same graph. See clause 11.2 of [ITU-T Z.101].

NOTE 1 – A *State-name* is defined to be the same as a *Name*.

$\forall sn \in \text{State-node}: \forall svi, svi1 \in \text{Save-signalset}: \forall in, in1 \in \text{Input-node}:$   
 $(svi \neq svi1) \wedge (svi.\text{parentAS1} = sn) \wedge (svi1.\text{parentAS1} = sn) // svi \text{ and } svi1 \text{ in same state node}$   
 $\wedge (in \neq in1) \wedge (in.\text{parentAS1} = sn) \wedge (in1.\text{parentAS1} = sn) // in \text{ and } in1 \text{ in same state node}$   
 $\Rightarrow$   
( *in.s2-Identifier* = undefined  $\Rightarrow //$  input has no gate implies  
( ((*in.s1-Identifier*  $\neq$  *in1.s1-Identifier*)  $\vee$  (*in1.s2-Identifier*  $\neq$  undefined)) // *in1* different signal or has gate  
 $\wedge$  ((*in.s1-Identifier*  $\neq$  *svi.s1-Identifier*)  $\vee$  (*svi.s2-Identifier*  $\neq$  undefined)) // *svi* diff. signal or has gate  
 $\wedge$  ((*in.s1-Identifier*  $\neq$  *svi1.s1-Identifier*)  $\vee$  (*svi1.s2-Identifier*  $\neq$  undefined)) // *svi1* diff. signal or has gate  
) )  
 $\wedge$   
( *in.s2-Identifier*  $\neq$  undefined  $\Rightarrow //$  input has a gate implies  
( (*in.s1-Identifier*  $\neq$  *in1.s1-Identifier*) // different signal in *in1*  
 $\vee$  (*in.s2-Identifier*  $\neq$  *in1.s2-Identifier*) // different gate in *in1* (including undefined gate)  
 $\vee$  (*in.s1-Identifier*  $\neq$  *svi.s1-Identifier*) // different signal in *svi*  
 $\vee$  (*in.s2-Identifier*  $\neq$  *svi.s2-Identifier*) // different gate in *svi* (including undefined gate)  
 $\vee$  (*in.s1-Identifier*  $\neq$  *svi1.s1-Identifier*) // different signal in *svi1*  
 $\vee$  (*in.s2-Identifier*  $\neq$  *svi1.s2-Identifier*) // different gate in *svi1* (including undefined gate)  
) )

In the following, *Save-item* and *Input-node* refer, respectively, to a *Save-item* of the *Save-signalset* of a basic *State-node* and an *Input-node* of the *Input-node-set* of the same basic *State-node*. If an *Input-*

*node* has no *Gate-identifier*, the *Signal-identifier* of that *Input-node* shall not appear without a *Gate-identifier* in another *Input-node* or a *Save-item*. If an *Input-node* has a *Gate-identifier*, the *Signal-identifier* of that *Input-node* shall not appear with the same *Gate-identifier* in another *Input-node* or a *Save-item*. See clause 11.2 of [ITU-T Z.101].

NOTE 2 – Both *Signal-identifier* and *Gate-identifier* are defined to be the same as an *Identifier*. In both *Input-node* and *Save-item*, the *Signal-identifier* is followed by an optional *Gate-identifier* and are therefore selected by *s1-Identifier* and *s2-Identifier* respectively.

## Concrete syntax

```
<state> ::
    <state list>
    { <connect part>
    | <continuous signal>
    | <input part>
    | <priority input>
    | <save part>
    | <spontaneous transition>}*
    [ <state timer part> ]
```

NOTE 3 – Although the concrete grammar allows <continuous signal> and <spontaneous transition> for a <state> with a <state list item> that is a <typebased composite state> or <composite state list item>, for a composite state in the abstract grammar *Spontaneous-transition* and *Continuous-signal* are not allowed, therefore they are only valid for basic state items.

```
<state list> ::
    {<basic state name> | <typebased composite state> | <composite state list item>}+
    | <asterisk state list>

<basic state name> = <basic state<name>>

<composite state list item> :: <composite state name> <nextstate parameters>

<composite state name> = <composite state<name>>

<asterisk state list> :: <state<name>>*

<state timer part> ::
    [ <virtuality> ] <state timer> <transition>

<state timer> = <Time<expression>> | <set clause>
```

## Conditions on concrete syntax

$$\forall bs \in \langle \text{state} \rangle : \forall sn \in \langle \text{name} \rangle : \\ (sn.parentAS0 = bs.s-\langle \text{state list} \rangle \wedge bs.s-\langle \text{state list} \rangle \in \langle \text{asterisk state list} \rangle) \Rightarrow \\ (\forall sn1 \in \langle \text{name} \rangle (sn.parentAS0 = sn1.parentAS0) \Rightarrow (sn \neq sn1)) \wedge \\ (sn \in bs.surroundingScopeUnit0.stateNameSet0)$$

The <state name>s in an <asterisk state list> shall be distinct and shall be contained in other <state list>s in the enclosing body or in the body of a supertype. See clause 11.2 *Concrete grammar* of [ITU-T Z.103].

$$\forall s1, s2 \in \langle \text{state} \rangle : \\ (\exists sn \in \langle \text{name} \rangle : (sn \in s1.stateNameSet0 \wedge sn \in s2.stateNameSet0)) \Rightarrow \\ ( (s1.s-\langle \text{state timer part} \rangle = \text{undefined}) \\ \vee (s2.s-\langle \text{state timer part} \rangle = \text{undefined}) \\ \vee (s1.s-\langle \text{state timer part} \rangle = s1.s-\langle \text{state timer part} \rangle))$$

When two <state> items contain the same <state name>, a <state timer> shall not be specified for both <state> items or both <state> items shall specify the same <state timer>. See clause 11.2 *Concrete grammar* of [ITU-T Z.102].

## Transformations

$$\langle \langle \text{state} \rangle (\langle s \rangle \hat{\ } rest, triggers, timer) \rangle$$

```

provided rest ≠ empty
=8=>
< mk-<state>(< s >, triggers, timer), mk-<state>(rest, triggers, timer) >

```

When the <state list> of a <state> contains more than one <state name>, a copy of that <state> is created for each such <state name>. Then the <state> is replaced by these copies. See clause 11.2 *Model* of [ITU-T Z.103].

```

< <state>(< s >, triggers1, timer1) > ^ rest ^ < <state>(< s >, triggers2, timer2) >
=15=>
rest ^ < mk-<state>(< s >, triggers1 ^ triggers2, if timer1 ≠ undefined then timer1 else timer2 endif) >

```

When two <state> items that each contain one <state name>, contain the same <state name>, these <state> items are concatenated into one <state> having that <state name> with the <state timer> specified for one (or both if it is the same) <state> items. See clause 11.2 *Model* of [ITU-T Z.103].

```

<composite state list item>(name, nextstateparams)
provided mk-<identifier>(name.surroundingQualifier0, name).anonCompStateTypeName ≠ undefined
=12=>
mk-<typebased composite state>(
  name,
  nextstateparams,
  mk-<type expression>(
    mk-<identifier>(name.surroundingQualifier0, // qualifier of type expression base type
      mk-<identifier>(name.surroundingQualifier0, name).anonCompStateTypeName // name base type
    ), // base type identifier
    empty // empty actual context parameters
  ) // type expression
) // typebased composite state

```

A <composite state list item> is a shorthand that is transformed to a <typebased composite state> that defines the name and an <composite state type<identifier> that references a <composite state type definition> transformed from the <composite state definition>. See clause 11.2 *Model* of [ITU-T Z.102].

```

b=<state>(<asterisk state list>(exceptStates), triggers)
=15=>
mk-<state>(< s ∈ ((b.surroundingScopeUnit0.stateNameSet0) \ (exceptStates.toSet)) >, triggers)

```

A <state> with an <asterisk state list> is transformed to a list of <state>s, one for each <state name> of the body in question, except for those <state name>s contained in the <asterisk state list>. See clause 11.2 *Model* of [ITU-T Z.103].

```

st.stateTimerIdentifier
provided
  st ∈ <state>
  ^ st.s-<state timer part> ≠ undefined // expression or set clause
  ^ st.stateTimerIdentifier = undefined
=8=>
  (stateTimerIdentifier\{( st, undefined )})
  ∪ { ( st,
    if st.s-<state timer part>.s-<state timer> ∈ <expression>
    then newName // expression – implicit name for parameterless timer definition
    else st.s-<state timer part>.s-<state timer>.s-<identifier> // set clause – timer name
    endif
  ) }

stm=<state timer>(exprn)
provided
  exprn ∈ <Time><expression>
=8=>

```

```

if exprn ∈ <expression> then
  mk-<state timer>( mk-<set clause>( exprn, st.stateTimerIdentifier, empty))
else // set clause
  stm
endif
and
entities = parentASOfKind(stm,
  <system type definition>
  ∪ <block type definition>
  ∪ <process type definition>).s-<agent structure>.s-<entity in agent>-seq
=>
entities ^ // add implicitly named parameterless timer definition to agent
mk-<timer definition> (< mk-<timer definition item>( st.stateTimerIdentifier, empty, undefined) >)

```

A <state timer> with **state timer** <Time expression> is equivalent to <state timer> with a <set clause> that has an implicitly named, parameterless timer definition, which is set to the <Time expression>. See clause 11.2 *Model* of [ITU-T Z.102].

### Mapping to abstract syntax

```

| <state>( < <basic state name>( name, ) >, triggers, statetimerpart) then
let TriggerSet = { Mapping(triggers[i]): i=1..triggers.length }
in
mk-State-node(Mapping(name), // State-name
  { ss ∈ TriggerSet: ss ∈ Save-signalset }, // Save-signalset
  { in ∈ TriggerSet: in ∈ Input-node-set }, // Input-node-set
  // a basic state has (possibly empty) continuous signal or spontaneous transition sets
  { { cs ∈ TriggerSet: cs ∈ Continuous-signal }, // Continuous-signal-set
    { sp ∈ TriggerSet: sp ∈ Spontaneous-transition } // Spontaneous-transition-set
  },
  Mapping(statetimerpart)
)
endlet // TriggerSet

```

NOTE 4 – A <state> with a <composite state list item> is transformed to a <state> with a <typebased composite state> before mapping takes place.

```

| <state>( < <typebased composite state>( name, basetypeid) >, triggers, statetimerpart) then
let TriggerSet = { Mapping(triggers[i]): i=1..triggers.length }
in
mk-State-node(Mapping(name),
  { ss ∈ TriggerSet: ss ∈ Save-signalset },
  { in ∈ TriggerSet: in ∈ Input-node },
  // a state with a typebased composite state shall not have continuous signals or spontaneous transitions
  { Mapping(basetypeid),
    { cn ∈ TriggerSet: cn ∈ Connect-node }
  },
  Mapping(statetimerpart)
)
endlet // TriggerSet

| stp = <state timer part>(*, statetimer, transition) then
if statetimer ∈ <expression>
then // state timer - time expression
  mk-State-timer(
    Mapping(statetimer), // Time-expression
    Mapping(parentASOfKind(stp, <state>).stateTimerIdentifier), // Timer-identifier
    empty, // empty Expression list
    Mapping(transition)
  )
else // state timer - set clause
  mk-State-timer(

```

```

if statetimer.s-<expression> ≠ undefined // set clause has time expression
then Mapping(statetimer.s-<expression>) // Time-expression
else // no Time expression -use default value of timer
  Mapping(
    mk-<operator application>(mk-<operator identifier>(predefinedQual0("Time"), ""+""),
      now,
      statetimer.s-<identifier>.refersto0.s-<timer default initialization>
    )
  ) // Time-expression
endif, // Time expression present/absent
Mapping(statetimer.s-<identifier>), // Timer-identifier
Mapping(statetimer.s-<expression>-seq) // set cause Expression list (possibly empty)
Mapping(transition)
)
endif // state timer kind

```

## Auxiliary functions

The auxiliary function *stateTimerIdentifier* stores the name of a state timer for a state.

```

controlled stateTimerIdentifier: <state> → <identifier>
initially ∇ s ∈ <state>: s.stateTimerIdentifier = undefined

```

The function *stateNameSet0* gets the set of <state name> items of a state, an agent definition, an agent type definition, a composite state, a composite state type definition or a procedure definition.

```

stateNameSet0(d: <state> ∪ <agent definition> ∪ <agent type definition> ∪ <composite state definition> ∪
  <composite state type definition> ∪ <internal procedure definition>): <name>-set =def
if (d ∈ <state>) then
  if d.s-<state list> ∈ <asterisk state list> then
    d.surroundingScopeUnit0.stateNameSet0{n ∈ <name>: n.parentAS0 = d.s-<state list>}
  else // d.s-<state list> ∈ {<basic state name>|<composite state list item>|<typebased composite state>}+
    {n ∈ <name>: n.parentAS0 = d.s-<state list>}
  endif
else {n ∈ <name>: ∃ s ∈ <state>: (s ∈ d.stateSet0) ∧ (n ∈ s.stateNameSet0)}
endif

```

### F2.2.8.3 Input

#### Abstract syntax

```

Input-node :: [ Priority-name ]
              Signal-identifier [ Gate-identifier ]
              [ Provided-expression ]
              [ In-choice ]
              [ Variable-identifier ]*
              Transition

In-choice :: Variable-identifier

```

#### Conditions on abstract syntax

```

∇ in ∈ Input-node: ∇ sd ∈ Signal-definition:
  sd = getEntityDefinition1(in.s-Signal-identifier, signal) ⇒
    (in.s-Variable-identifier-seq.length = sd.s-Signal-parameter-seq.length) ∧
    (∇ i ∈ 1..in.s-Variable-identifier.length:
      ∃ vd ∈ Variable-definition: vd = getEntityDefinition1(in.s-Variable-identifier[i], variable) ∧
        isCompatibleTo1(vd.s-Sort-reference-identifier, sd.s-Sort-reference-identifier[i]))

```

The length of the list of optional *Variable-identifier* items shall be the same as the number of *Signal-parameter* items in the *Signal-definition* denoted by the *Signal-identifier*. The sorts of the variables shall correspond by position to the sorts of the data items that are carried by the signal. See clause 11.3 *Abstract grammar* of [ITU-T Z.101].

## Concrete syntax

```

<input part> ::
    [<virtuality>] <input list> [<enabling condition>] <transition>

<input list> ::
    { <stimulus> [ <in choice> ] [ <priority clause> ] }+
    | <asterisk input list> [ <in choice> ] [ <priority clause> ]
    | <encoded input>

<stimulus> :: <signal list item> [<variable>]* [<via path>]

<asterisk input list> :: {}

<via path> :: <channel><identifier> | <gate><identifier>

<in choice> :: <choice><variable> | <signal expression>

<encoded input> :: <variable> [ <encoding path> ]

```

## Conditions on concrete syntax

$$\forall s \in \langle \text{state} \rangle: |s.\text{asteriskInputListSet0}| \leq 1$$

A  $\langle \text{state} \rangle$  shall contain at most one  $\langle \text{asterisk input list} \rangle$ . See clause 11.3 *Concrete grammar* of [ITU-T Z.103].

$$\forall s \in \langle \text{state} \rangle: (s.\text{asteriskInputListSet0} = \emptyset) \vee (s.\text{asteriskSaveListSet0} = \emptyset)$$

A  $\langle \text{state} \rangle$  shall not contain both  $\langle \text{asterisk input list} \rangle$  and  $\langle \text{asterisk save list} \rangle$ . See clause 11.3 *Concrete grammar* of [ITU-T Z.103].

$$\forall \text{stim} \in (\langle \text{input part} \rangle \cup \langle \text{priority input} \rangle): \forall \text{sli} \in \langle \text{signal list item} \rangle:$$

```

    isAncestorAS0(stim, sli)  $\Rightarrow$ 
        (let idKind = sli.s-<identifier>.idKind0 in
            (idKind  $\neq$  remote variable)  $\wedge$ 
            (idKind = remote procedure  $\vee$  idKind = signallist  $\Rightarrow$ 
                sli.parentAS0.s-<variable>-seq=empty)
        endlet)

```

A  $\langle \text{signal list item} \rangle$  of a  $\langle \text{stimulus} \rangle$  (of an  $\langle \text{input list} \rangle$  or  $\langle \text{priority input} \rangle$ ) shall not denote a  $\langle \text{remote variable identifier} \rangle$  and if it denotes a  $\langle \text{remote procedure identifier} \rangle$  or a  $\langle \text{signal list identifier} \rangle$ , the  $\langle \text{stimulus} \rangle$  parameters (including the parentheses) shall be omitted. See clause 10.4 *Concrete grammar* of [ITU-T Z.102].

$$\forall v \text{ in } \langle \text{stimulus} \rangle.\text{s-<variable>-seq}: \neg(\text{isGlobalBlockVar0}(v))$$

A  $\langle \text{variable} \rangle$  of a  $\langle \text{stimulus} \rangle$  shall not be a global variable of a system (type) or block (type) except if the  $\langle \text{stimulus} \rangle$  is within the state machine actions of system (type) or block (type). See clause 11.3 *Concrete grammar* of [ITU-T Z.101].

$$\forall \text{chid} \in \{ id = \text{stim.s-<via path>.s-<identifier>} :$$

```

    stim  $\in$  ( <stimulus>  $\cup$  <save item> )  $\wedge$ 
    id.refersto0  $\in$  <channel definition>  $\wedge$  // not a gate definition
    stim.surroundingScopeUnit0  $\in$  <composite state type definition> } // only when in composite state type
:
(  $\exists!$ gid  $\in$ 
    ( reachableSmGates(chid.refersto0.s1-<channel path>.s2-<channel endpoint>.s-<gate>,
        chid.surroundingScopeUnit0)
     $\cup$ 
    if chid.refersto0.s2-<channel path>  $\neq$  undefined
    then reachableSmGates(chid.refersto0.s2-<channel path>.s2-<channel endpoint>.s-<gate>,
        chid.surroundingScopeUnit0)
    else  $\emptyset$ 
    endif
    )
:

```

```

    ( gid.refersto.s-<gate constraint>.direction0 = in ∧
      chid.parentAS0.parentAS0 in gid.refersto.s-<gate constraint>.s1-<signal list>
    )
  )
)

```

The <channel><identifier> for a <via path> of a <stimulus> or <save item> in a composite state type (that is, after application of the models for agent definition, agent structure with an interaction and channel to channel connection) shall identify a channel such that the enclosing state machine of the via path is reachable from the channel with the signal given in the stimulus or save through exactly one gate of the state machine. See clause 11.3 *Concrete grammar* of [ITU-T Z.103].

```

∀chid ∈ { id = cc.s-<via path>.s-<identifier> :
  cc ∈ <communication constraints> ∧
  id.refersto0 ∈ <channel definition> ∧ // not a gate definition
  cc.surroundingScopeUnit0 ∈ <composite state type definition> } // only when in composite state type
:
( ∃!gid ∈
  ( reachableSmGates(chid.refersto0.s1-<channel path>.s2-<channel endpoint>.s-<gate>,
    chid.surroundingScopeUnit0)
    ∪
    if chid.refersto0.s2-<channel path> ≠ undefined
    then reachableSmGates(chid.refersto0.s2-<channel path>.s2-<channel endpoint>.s-<gate>,
      chid.surroundingScopeUnit0)
    else ∅
    endif
  )
:
( gid.refersto.s-<gate constraint>.direction0 = in ∧
  chid.parentAS0.parentAS0 in gid.refersto.s-<gate constraint>.s1-<signal list>
)
)
)

```

A <channel><identifier> for a <via path> of <communication constraints> output in a composite state type (that is, after application of the models for agent definition, agent structure with an interaction, channel to channel connection, remote procedure and import expressions) shall identify a channel such that the enclosing state machine of the via path is reachable from the channel with the signal given in the stimulus or save through exactly one gate of the state machine. See clause 11.3 *Concrete grammar* of [ITU-T Z.103].

```

∀chid ∈ { id ∈ <identifier> : id.parentAS0 ∈ <via path> ∧ id.refersto0 ∈ <channel definition> } :
  (let ch = chid.refersto0 in
    (ch.s2-<channel path> ≠ undefined) // bidirectional
  ⇒
  ( ch.s1-<channel path>.s2-<channel endpoint>.s-<identifier>.refersto0 ∉ (<state machine> ∪ this) ) ∨
  ( ch.s1-<channel path>.s2-<channel endpoint> ≠ ch.s2-<channel path>.s2-<channel endpoint> )
  endlet) // ch

```

If a <via path> has a <channel> identifier this shall not be a bidirectional channel with both ends connected to the same state machine. See clause 11.3 *Concrete grammar* of [ITU-T Z.103].

```

∀s ∈ <state>: ((∃ ec ∈ <encoded input>: isAncestorAS0(s, ec)) ⇒
  ( ∀stim ∈ {st: st ∈ <stimulus> ∧ isAncestorAS0(s, st)}: (stim.s-<via path> ≠ undefined)
  ∧
  ∀svit ∈ {si: si ∈ <save item> ∧ isAncestorAS0(s, si)}: (svit.s-<via path> ≠ undefined)
  ))

```

If an <encoded input> is given for a path (a channel or gate), the messages received from that path are received and stored in the variable given in their encoded form. It is allowed to specify these signals in other inputs or saves of the same state only if a <via path> is specified. See introduction in clause 11.3 of [ITU-T Z.104].

```

ei ∈ <encoded input> ∧ ei.s-<encoding path> = undefined

```

```

⇒
let eicontext = parentAS0ofKind(ei, // context of encoded input
    <block definition> ∪ <block type definition>
    ∪ <composite state definition> ∪ <composite state type definition>
    ∪ <process definition> ∪ <process type definition>
    ∪ <system type definition> ) in
// if the context is an agent definition or composite state definition,
// consider the channels in the scope enclosing the agent/comp state that are connected to the agent/state, else
// if the context is an agent type definition, composite state type definition consider the gates of the type
if eicontext ∈ (<block definition> ∪ <composite state definition> ∪ <process definition>) then
|{encodedch: encodedch ∈ <channel definition>

    ∧ ( (encodedch.s1-<channel path>.s2-<channel endpoint>.refersto0 = eicontext) // fwd to agent/state
        ∨ (encodedch.s2-<channel path>.s2-<channel endpoint>.refersto0 = eicontext) // rev to agent/state
        )
    }|= 1 // number of channels from agent/state with encoding
else // block, composite state, process or system type
|{encodedgt: encodedgt ∈ (<textual gate definition> ∪ <textual interface gate definition>)
    ∧ encodedgt.s-<encoding rules> ≠ undefined
    ∧ if encodedgt ∈ <textual gate definition>
        then encodedgt.s-<gate constraint>.direction0 = in
        else encodedgt.s-implicit = in
        endif
    ∧ parentAS0ofKind(encodedgt, <block type definition> // context of encoding expression
        ∪ <composite state type definition> ∪ <process type definition> ∪ <system type definition>)
        = eicontext // gate defined in type that is context of ee
    }|= 1 // number of gates from agent/state type with encoding
endlet // eicontext

```

If the <encoding path> is omitted from <encoded input>, there shall be exactly one path with encoding leading to the context of the input that has a set of encoding rules that produces the sort (*Charstring*, *Octetstring* or *Bitstring*) of the <variable>. Otherwise the <encoding path> shall have a set of encoding rules that produces the sort (*Charstring*, *Octetstring* or *Bitstring*) of the <variable>.

$$\forall v \in \langle \text{encoded input} \rangle . s \langle \text{variable} \rangle : \neg(\text{isGlobalBlockVar0}(v))$$

A <variable> of an <encoded input> shall not be a global variable of a system (type) or block (type) except if the <encoded input> is within the state machine actions of system (type) or block (type). See clause 11.3 *Concrete grammar* of [ITU-T Z.104].

```

∀iplist ∈ <input list>: (
    ( iplist.s-implicit.s-<asterisk input list> = undefined // not asterisk input list
      ∧ iplist.s-implicit ∉ <encoded input> // not encoded input
    ) ⇒ // iplist is (stimulus, in choice, priority clause) list and implies
    ∀ipitem in iplist.s-implicit: (
        ( ipitem.s-<in choice> ≠ undefined
          ∧ ipitem.s-<signal list item>.refersto0 ∈ <signal definition> //only check when transformed to signal
        ) ⇒
        ( let chdef = ipitem.s-<in choice>.s-<variable>.getVariableSort0.refersto0 in
          let assig = ipitem.s-<signal list item>.asSignal.s-<name> in
            chdef ∈ <choice definition>
            ∧ ((∃ i ∈ 1..chdef.s-<choice of sort>-seq.fieldNameListCh0.length) : (
                assig = chdef.s-<choice of sort>-seq.fieldNameListCh0[i]
                ∧ assig = chdef.s-<choice of sort>-seq.fieldSortListCh0[i]
            ))
          endlet // assig
          endlet // chdef
        ) // for each ipitem
    ) // for each input list

```

NOTE 1 – The condition is checked as true only for the situation when the <signal list item> refers to a signal definition. If the <signal list item> was an <interface-identifier>, the enclosing <input part> is transformed to

a list of <input part> items – one for each signal of the interface. If the <signal list item> is for remote procedure or remote variable, this is transformed into an exchange of signals.

The <choice variable> of an <in choice> shall have a choice data type that includes fields where all the signals that are mentioned in the <stimulus> are covered: that is, for each signal (for example, with the identity signal\_id) there shall be a field with the unique name denoted by an <as signal> for the signal (**as signal** signal\_id) and the data type defined by <as signal> for the signal (**as signal** signal\_id). See clause 11.3 *Concrete grammar* of [ITU-T Z.104].

$\forall v \in \langle \text{in choice} \rangle.s\text{-}\langle \text{variable} \rangle: \neg(\text{isGlobalBlockVar0}(v))$

A <variable> of an <in choice> shall not be a global variable of a system (type) or block (type) except if the <in choice> is within the state machine actions of system (type) or block (type). See clause 11.3 *Concrete grammar* of [ITU-T Z.104].

## Transformations

```

<input part>(virt, <input list>( < <stimulus>( <signal list item>(id), varlist, path), choice, pri >), cond, trans)
provided id.refersto0 ∈ <interface definition>
=8=>
< mk-<input part>(virt, mk-<input list>(
  < mk-<stimulus>( sig, varlist, path) , choice, pri >), cond, trans)
| sig in id.refersto0.s-<signal list item>-seq
>

```

NOTE 2 – The above transform takes place after any <input part> with more than one <stimulus> has been transformed to an <input part> list with one <stimulus> in each <input part> (see below). The <input part> is then transformed to a list of <input part> items, one for each signal of the <interface definition>. The transform above covers the conditions in the two text paragraphs below in the case of an <input list>.

```

<priority input>(virt, <priority input list>(
  < <priority stimulus>( <stimulus>( <signal list item>(id), varlist, path), choice, pri) >
), trans
) // priority input
provided id.refersto0 ∈ <interface definition>
=8=>
< mk-<priority input>(virt, mk-<priority input list>(
  < mk-<priority stimulus>( mk-<stimulus>( sig, varlist, path), choice, pri) >
), trans
) // priority input
| sig in id.refersto0.s-<signal list item>-seq
>

```

NOTE 3 – The above transform takes place after any <priority input> with more than one <priority stimulus> in the <priority input list> has been transformed to a list of <priority input> items with one <priority stimulus> in each <priority input> (see clause F2.2.8.4). The <priority input> is then transformed to a list of <priority input> items, one for each signal of the <interface definition>. The transform above covers the conditions in the next two text paragraphs in the case of an <priority input list>.

A <stimulus> whose <signal list item> is an <interface<identifier> is derived syntax for a list of <stimulus> items that replaces the <interface<identifier> in the enclosing <input list> or <priority input list>. In this list, there is a one to one correspondence between the <stimulus>s and the members of the signal list. See clause 11.3 *Model* of [ITU-T Z.103].

When applying the model for an <interface identifier> as a <signal list item> of a <stimulus> the <in choice> is added after each <stimulus>. See clause 11.3 *Model* of [ITU-T Z.104].

```

<input part>(virt, <input list>(inputItems), cond, trans)
provided
  inputItems.s-<asterisk input list> = undefined // not asterisk
  ^ inputItems ∉ <encoded input > // not encoded, therefore stimulus list
  ^ inputItems.length > 1

```

```

=8=>
mk-<input part>(virt, mk-<input list>(< inputItems.head >), cond, trans) ^
if inputItems.length > 1
then mk-<input part>(virt, mk-<input list>(inputItems.tail, cond, trans)
else empty
endif

```

When the <stimulus> list of an <input part> contains more than one <stimulus>, a copy of the <input part> is created for each such <stimulus>. Then the <input part> is replaced by these copies. See clause 11.3 *Model* of [ITU-T Z.103].

```

<input part>(virt, <input list>(< (stim, choice, pri) >), *, trans) provided pri ≠ undefined
=8=>
mk-<priority input>(virt, mk-<priority input list>(< (stim, choice, pri) >), trans)

```

In an <input part> with one <stimulus>, if the <stimulus> is followed by a <priority clause>, the input symbol is replaced by a <priority input> containing the <stimulus> followed by the <priority clause>. See clause 11.3 *Model* of [ITU-T Z.103].

```

v.anonCompVar
provided
v ∈ (<indexed variable> ∪ <field variable>) ∧
(∃ ip ∈ <input part>:(v in stm.s-<variable>-seq ∧ stm ∈ <stimulus> ∧ stm in ip.s-<input list>.s-implicit)) ∧
v.anonCompVar = undefined
=8=>
(anonCompVar\{( v, undefined )} ) ∪ {( v, newName)}

```

```

ip = <input part>(virt, <input list>(< (<stimulus>(item, vars, path), choice, pri) >), cond, trans)
provided
{ v ∈ vars.toSet: v ∈ (<indexed variable> ∪ <field variable>) ∧ v.anonCompVar ≠ undefined } ≠ ∅
// one or more of the stimulus variable items of a <stimulus> is an indexed/field variable
// and anonymous name allocated for indexed/field variable
=8=>
let newvars =
< (if v ∈ (<indexed variable> ∪ <field variable>) then v.anonCompVar else v endif) : v in vars >
in
mk-<input part>(
  virt,
  mk-<input list>(< (mk-<stimulus>(item, newvars, path), choice, pri) >),
  cond,
  if trans ∈ <transition action items>
  then // put assigns from newvars to vars before actions and terminator
    mk-<transition action items>(
      < assignNewvarsToExtendedVars0(vars, newvars) > ^ trans.s-<action>-seq,
      trans.s-<terminator>) // transition action items
    else // transition was just a terminator, // put assigns from newvars to vars before terminator
      mk-<transition action items>( < assignNewvarsToExtendedVars0(vars, newvars) >, trans)
    endif
) // <input part>
endlet // newvars
and
items = parentAS0ofKind(ip, SCOPEUNIT0).getEntities0
=>
// add implicitly defined variable definitions to the surrounding scope
items ^ defineNewvars0(vars,
  < (if v ∈ (<indexed variable> ∪ <field variable>) then v.anonCompVar else v endif) : v in vars >
) // defineNewvars0

```

When one or more of the stimulus variable items of a <stimulus> is an <extended variable> (an <indexed variable> or <field variable>), then each <extended variable> is replaced by a unique, new, anonymous implicitly declared <variable<identifier> of the same sort as the original <extended

variable>. Directly following the input area (<input area> or <priority input area>), a <task area> is inserted which in its <task body> contains an <assignment statement> for each of the <extended variable> items, assigning the result of the corresponding new variable to the <extended variable>. The results are assigned in the order from left to right of the <extended variable> list. This <task area> becomes the first <action area> in the <transition area> of the input area. See clause 11.3 *Model* of [ITU-T Z.103].

```

< ip = <input part>( virt, <input list>(a = <asterisk input list>, choice, pri), cond, trans) >
provided
  parentAS0ofKind(ip,<state>).s-<state list> ∉ <asterisk state list> ∧
  parentAS0ofKind(ip,<state>).s-<state list>.length= 1
=8=>
<
  if pri = undefined
  then
    mk-<input part>(
      virt,
      mk-<input list>(
        < mk-<stimulus>(item, undefined, undefined), choice, undefined)
      > ), //input list
      cond,
      trans
    ) // input part
  else
    mk-<priority input>(
      virt,
      mk-<priority input list>(
        < mk-<priority stimulus>(item, undefined, undefined), choice, pri)
      > ), // priority input list
      trans
    ) // priority input
  endif
  : item ∈ (explicitValidInputSigs0(parentAS0ofKind(ip,<agent type definition>)) \
    { sig ∈ <signal list item>:
      parentAS0ofKind(sig,<state>) = st ∧
      parentAS0ofKind(ip,<state>).s-<state list>.head in st.s-<state list> // same state
    } // set of signals in other inputs or saves of state
  ) //
> // replacement list of input parts

```

An <asterisk input list> is transformed to a list of <input part>s, one for each member of the complete valid input signal set of the enclosing <agent definition>, except for <signal identifier>s of implicit input signals introduced by the concepts in clauses 10.5 and 10.6 of [ITU-T Z.102] and for <signal identifier>s contained in the other <input list>s and <save list>s of the <state>.

When applying the model for <asterisk input list>, the <in choice> is added after each <stimulus>. See clause 11.3 *Model* of [ITU-T Z.104].

```

vp = <via path>( chid)
provided

    | <channel definition> then // path is channel
        if def.s1-<channel path>.s2-<channel endpoint>.refersto0 = eicontext // fwd to agent/state
        then def.s1-<channel path>.s2-<channel endpoint>.s-<signal list>.toSet
        else def.s2-<channel path>.s2-<channel endpoint>.s-<signal list>.toSet // rev to agent/state
        endif
    | <gate definition> then // path is gate
        if def ∈ <textual gate definition>
        then def.s-<gate constraint>.s-implicit.s1-<signal list>.toSet // in gate
        else def.s-<identifier>.refersto0.usedSignalSet0
        endif
    otherwise // encoding path specified by interface
        ep.s1-<identifier>.refersto0.usedSignalSet0
    endcase // channel, gate or interface encoding path
>
endlet // assAction
endlet // eicontext

```

An <input part> for an <encoded input> is transformed to list of <input part> items, one for each signal that is receivable with the <encoded input>. For each of the signals that are receivable from the gate or channel specified in an <encoded input>, there is an <input part> with an <input list> item for the signal, an <in choice> item for the implicit **signal** variable and a <via path> for the gate or channel. For each of the signals of an interface identified by an <interface identifier> of an <encoding path> of an <encoded input>, there is an <input part> with an <input list> item for the signal, an <in choice> item for a <signal expression> and an undefined <via path>. Each revised <input part> contains the same <enabling condition> as the original <input part> for the <encoded input>. The <transition> of each revised <input part> contains a task, where the <variable> given in the <encoded input> is assigned the value of an <encoding expression> for the value in the implicit **signal** variable and the <encoding path> of the <encoding expression>. This task is followed by the original transition for the <encoded input>. See clause 11.3 *Model* of [ITU-T Z.104].

For each of the signals that are receivable from the gate or channel specified in an <encoded input>, there is an implied input with a <via path> for the gate or channel.

NOTE 4 – If the <encoding path> is specified by an <interface identifier> **with** <rules identifier>, because the <encoded input> is transformed into inputs for the signals of the identified interface, no other input or save of the state is allowed to mention the same signals.

NOTE 5 – The introduction to clause 11.3 of [ITU-T Z.104] states: "Although the model given below describes the signals as first being decoded and then encoded again, it is expected that real implementations will optimize this to copying the encoded value to the variable given in the <encoded input>."

## Mapping to abstract syntax

```
| <input part>(*, < <stimulus>(item, vars, vp), choice, undefined >, cond, trans) then
  mk-Input-node(undefined, // no priority name – see mapping of priority input
    Mapping(item), // signal identifier
    Mapping(vp), // optional gate identifier
    Mapping(cond), // enabling condition -> optional provided expression
    Mapping(choice), // optional in choice
    < Mapping(vars[i] : i ∈ 1..vars.length >, // list - each element is a Variable-identifier or undefined
    Mapping(trans)) // transition

| <via path>( id) then Mapping(id)

| <in choice>( var ) then
  mk-In-choice(
    if var ∈ <variable>
    then Mapping(var)
    else // var is <signal expression> - access the agent variable #signal
      mk-Identifier(
        Mapping(parentAS0ofKind(name, <agent type definition>).fullQualifierWithin0),
        mk-Name("#signal")
      ) // mk-Identifier
    endif
  ) // mk-In-choice
```

## Auxiliary functions

Find the explicit valid input signal set of an <agent type definition> (that is, a system type definition, a block type definition or process type definition). The explicit valid input signal set is the complete valid input signal set (see clause 9 *Semantics* of [ITU-T Z.101]) excluding implicit signals introduced and therefore includes:

- the set of signals in all channels or gates leading to the state machine of the agent;
- the valid input signal set defined explicitly for the agent;
- the valid input signal set defined explicitly for the state machine of the agent;
- the timer signals.

```
explicitValidInputSigs0(atd:<agent type definition>):<signal list item>-set =def
let stateMachine = atd.s-<agent structure>.s-<interaction>.s-<typebased composite state> in
let stateMachineId = mk-<identifier>(atd.fullQualifierWithin0, stateMachine.s-<name>) in
let chanSigs = {sig: sig in chPath.s-<signal list item>-seq ∧
  chPath ∈ <channel path> ∧ chPath.s2-<channel endpoint>= stateMachineId} in
let entitiesInCompType =
  if stateMachine.s-<type expression>.refersto0.s-implicit ∈ <composite state type graph>
  then stateMachine.s-<type expression>.refersto0.s-<composite state type graph>.
    s-<composite state structure>.s-<entity in composite state>-seq
  else stateMachine.s-<type expression>.refersto0.s-<state aggregation type>.
    s-<aggregation structure>.s-<entity in state aggregation>-seq
  endif
in
let gateSigs = {sig: sig in gate.s1-<signal list item>-seq ∧ gate.s-in ≠ undefined ∧
  gate ∈ <gate in definition> ∧ gate in entitiesInCompType}
in
let validSigInputSetAgent = {visa: visa in viss.s-<signal list item>-seq ∧
  viss ∈ <valid input signal set> ∧ viss in atd.s-<agent structure>.s-<entity in agent>-seq}
in
```

```

let validSigInputSetComp = { visc: visc in viss.s-<signal list item>-seq  $\wedge$ 
  viss  $\in$  <valid input signal set>  $\wedge$  viss in entitiesInCompType }
in
chanSigs  $\cup$  gateSigs  $\cup$  validSigInputSetAgent  $\cup$  validSigInputSetComp
endlet // validSigInputSetComp
endlet // validSigInputSetAgent
endlet // gateSigs
endlet // entitiesInCompType
endlet // chanSigs
endlet // stateMachineId
endlet // stateMachine

```

Make an action list that is assignments of new variables to extended variables.

```

assignNewvarsToExtendedVars0(varsl:<variable>*, newvarsl:<variable>*):<action>* =def
if varsl =empty then empty
else
  let v = varsl.head in
  let newv = newvarsl.head in
  if v  $\in$  (<indexed variable>  $\cup$  <field variable>)
  then
    // create an assignment of the result of the corresponding newv to the extended variable v
    <action>(undefined,<task>(assignment)(v, newv),undefined)  $\wedge$ 
    assignNewvarsToExtendedVars0(varsl.tail, newvarsl.tail)
  else assignNewvarsToExtendedVars0(varsl.tail, newvarsl.tail)
  endif
  endlet // newv
  endlet // v
endif

```

Definitions for new variables that replace extended variables in a stimulus.

```

defineNewvars0(varsl:<variable>*, newvarsl:<variable>*):<variable definition>* =def
if varsl =empty
then empty
else
  let v = varsl.head in
  let newv = newvarsl.head in
  if v  $\in$  (<indexed variable>  $\cup$  <field variable>)
  then
    // create a definition of the newv that corresponds to the extended variable v
    <variable definition>( <variables of sort>(PART, newv, getVariableSort0(v)))  $\wedge$ 
    defineNewvars0 (varsl.tail, newvarsl.tail)
  else defineNewvars0 (varsl.tail, newvarsl.tail)
  endif
  endlet // newv
  endlet // v
endif

```

Get the <asterisk input list> for a <state>.

```

asteriskInputListSet0(s: <state>): <asterisk input list>-set =def
{ ail  $\in$  <asterisk input list>: isAncestorAS0(s, ail) }

```

The function *reachableSmGates* is list of destination gates in instances of the composite state type reachable from the given gate. This function should be used only after any agent definition has been replaced by a typebased agent definition, and any agent structure with an agent body has been replaced by an agent structure with an interaction.

```

reachableSmGates(gid: <identifier>, cstd : <composite state type definition>):<identifier>-set =def
if gid.refersto0  $\notin$  <gate definition>
then  $\emptyset$ 

```

```

elseif gid.refersto0.surroundingScopeUnit0 = cstd
then { gid }
elseif gid.refersto0.surroundingScopeUnit0 ∈ <composite state type definition> // but not cstd
then ∅
elseif gid.refersto0.surroundingScopeUnit0 ∈
  ( <block type definition> ∪ <process type definition> ∪ <system type definition> )
then
  U{ if chdef.s1-<channel path>.s2-<channel endpoint>.s-<gate> = gid
    then reachableSmGates(chdef.s1-<channel path>.s1-<channel endpoint>.s-<gate>, cstd)
    else reachableSmGates(chdef.s1-<channel path>.s2-<channel endpoint>.s-<gate>, cstd)
    endif // find reachable state machine gates for the other channel endpoint
  : gid.refersto0.surroundingScopeUnit0 = chdef.surroundingScopeUnit0 ∧ // same scope as gate def
    ( chdef.s1-<channel path>.s1-<channel endpoint>.s-<gate> = gid // gate originates ch fwd path
      ∨ chdef.s1-<channel path>.s2-<channel endpoint>.s-<gate> = gid // or, gate terminates ch fwd path
    ) // rev path – if it exists – interchanges the gates
  } // take the distributed union of the set of sets
else ∅
endif

```

The function *anonCompVar* is a mapping from an indexed or extended variable to an anonymous name, used for a temporary variable to store a value to assign to the indexed or extended variable.

```

controlled anonCompVar: (<indexed variable> ∪ <field variable>) → <name>
initially ∇ v ∈ (<indexed variable> ∪ <field variable>) : v.anonCompVar = undefined

```

#### F2.2.8.4 Priority input

##### Concrete syntax

```

<priority input> ::
  [<virtuality>] <priority input list> <transition>

<priority input list> =
  <priority stimulus>+
  | <asterisk input list> [ <in choice> ] [ <priority clause> ]

<priority stimulus> :: <stimulus> [ <in choice> ] [ <priority clause> ]

<priority clause> :: [ <priority name> ]

<priority name> = <Natural name>

```

NOTE – In [ITU-T Z.103] clause 11.4 Priority Input, *Concrete grammar* <priority name> is defined as a <integer name>, which is equivalent to AS0 <Natural name>, because AS0 <name> includes the SDL-2010 lexical units <name>, <integer name> and <real name>.

##### Transformations

```

st = <state>( sl, parts, timer )
provided
  sl ∉ <asterisk state list> // not asterisk state list
  ∧ sl.length = 1 // only consider when state list reduced to one state
  ∧ ∃ pi in parts:
    ( pi ∈ <priority input>
      ∧ ( ( pstim in pi.s-<priority input list>.s-<priority stimulus>-seq // priority stimulus
          ∧ pstim.s-<priority clause> = undefined // no name given, just the keyword priority
        ) // true if there is an unnamed <priority clause> in <priority input list> of pi
        ∨
        ( pi.s-<priority input list>.s-<asterisk input list> ≠ undefined // asterisk
          ∧ pi.s-<priority input list>.s-<priority clause> = undefined
        ) // true if there is an unnamed <priority clause> in <asterisk input list> of pi
        ) // true if an unnamed <priority clause> in <asterisk input list> or <priority input list> of pi
      ) // true if there exists such an unnamed <priority clause> in parts
    =8=> // replace unnamed <priority clause> items of <priority input list> items in parts

```

```

let piNumSet = // set of priority input numbers explicitly defined in parts of st
  { pstim.s-<priority clause>.s-<priority name>.s-INTTOKEN0.intTokenToNat:
    pi in parts
    ^ pi ∈ <priority input>
    ^ pstim in pi.s-<priority input list>.s-<priority stimulus>-seq
    ^ pstim ≠ undefined // is defined - there is a priority input list with a priority stimulus
  } // priority numbers given by names in <priority stimulus> items
  ∪
  { pi.s-<priority input list>.s-<priority clause>.s-<priority name>.s-INTTOKEN0.intTokenToNat:
    pi in parts
    ^ pi ∈ <priority input>
    ^ pi.s-<priority input list>.s-<asterisk input list> ≠ undefined
  } // priority numbers given by names with <asterisk input list> items
in
let highest = take({n ∈ NAT
  : (¬∃ m : m ∈ piNumSet ∧ m > n) // not exists m
  }) // set for n, take
in
let newparts =
  < if parts[i] ∉ <priority input>
    then parts[i]
    elseif parts[i].s-<priority input list>.s-<priority stimulus>-seq.length > 0
    then // priority input with <priority stimulus>-seq
      let pstimlist = parts[i].s-<priority input list>.s-<priority stimulus>-seq
      in
      mk-<priority input>(
        parts[i].s-<virtuality>, // for <priority input>
        mk-<priority input list>
          (< if pstimlist[j].s-<priority clause> = undefined
            then
              mk-<priority stimulus>(
                pstimlist[j].s-<stimulus>,
                pstimlist[j].s-<in choice>,
                mk-<priority clause>(mk-<priority name>(natToIntToken(highest+1))))
            else pstimlist[j]
            endif
          : j ∈ 1..pstimlist.length
        >), // <priority stimulus> list for parts[i] <priority input list>
        parts[i].s-<transition>) // for <priority input>
      endlet // pstimlist
    else // priority input with asterisk input list
      if parts[i].s-<priority input list>.s-<priority clause> = undefined
      then mk-<priority input>(
        parts[i].s-<virtuality>, // for <priority input>
        mk-<priority input list>(
          parts[i].s-<asterisk input list>, // for <priority input list>
          parts[i].s-<in choice>, // for <priority input list>
          mk-<priority clause>( <priority name>( natToIntToken(highest+1)))),
        parts[i].s-<transition>) // for <priority input>
      else parts[i]
      endif
    endif
  : i ∈ 1..parts.length
  > // newparts list
in
mk-<state>(sl, newparts, timer)
endlet // newparts
endlet // highest
endlet // piNumSet

```

A <priority clause> without a <priority name> is transformed into a <priority clause> that is **priority** n, where n is one greater than the highest explicit <priority name> for a <priority stimulus> of the same state. The same value is used for all such transformations of the state, so that each priority stimulus without an explicit <priority name> has the same priority. See clause 11.4 *Model* of [ITU-T Z.103].

```

<priority input>(virt, stimulusList, trans)
provided stimulusList ∈ <priority stimulus>-seq ∧ stimulusList.length > 1
=8=>
mk-<priority input>(virt, < inputItems.head >, cond, trans) ^
if stimulusList.length > 1
then mk-<priority input>(virt, stimulusList.tail, cond, trans)
else empty
endif

```

When the <priority stimulus> list of a <priority input> contains more than one <priority stimulus>, a copy of the <priority input> is created for each such <priority stimulus>. Then the <priority input> is replaced by these copies. See clause 11.4 *Model* of [ITU-T Z.103].

```

< pi = <priority input>( virt, <priority input list>(a = <asterisk input list>, choice, pri), trans) >
provided
  parentAS0ofKind(pi,<state>).s-<state list> ∉ <asterisk state list> ∧
  parentAS0ofKind(pi,<state>).s-<state list>.length= 1
=8=>
<
  mk-<priority input>(
    virt,
    mk-<priority input list>(
      < mk-<priority stimulus>(item, undefined, undefined), choice, pri
    > ), // priority input list
    cond,
    trans
  ) // priority input
  : item ∈ ( explicitValidInputSigs0(parentAS0ofKind(ip,<agent type definition>)) \
    { sig ∈ <signal list item>:
      parentAS0ofKind(sig,<state>) = st ∧
      parentAS0ofKind(pi,<state>).s-<state list>.head in st.s-<state list> // same state
    } // set of signals in other inputs or saves of state
  ) //
> // replacement list of input parts

```

An <asterisk input list> in a <priority input list> is transformed to a <priority stimulus> list in the same way as an <asterisk input list> in an <input list> is transformed to a <stimulus> list.

### Mapping to abstract syntax

```

| <priority input>(*, <priority input list>( < <stimulus>(item, vars, vp), choice, pri > ), trans) then
  mk-Input-node(natToIntToken(pri.s-TOKEN),
    Mapping(item), // signal identifier
    Mapping(vp), // optional gate identifier
    undefined, // no enabling condition in a priority input
    Mapping(choice), // optional in choice
    < Mapping(vars[i] : i ∈ 1..vars.length >, // list - each element is a Variable-identifier or undefined
    Mapping(trans)) // transition

```

### F2.2.8.5 Continuous signal

#### Abstract syntax

```

Continuous-signal      ::      Continuous-expression
                          [ Priority-name ]
                          Transition

```

*Continuous-expression* = *Boolean-expression*  
*Priority-name* = *NAT*

### Concrete syntax

<continuous signal> ::  
 [<virtuality>] <continuous expression> [<priority name>] <transition>  
 <continuous expression> = Boolean<expression>

### Mapping to abstract syntax

| <continuous signal>(\*, *expr*, *prio*, *trans*) **then**  
**mk-Continuous-signal**(*Mapping*(*expr*), *Mapping*(*prio*), *Mapping*(*trans*))

#### F2.2.8.6 Enabling condition

### Abstract syntax

*Provided-expression* = *Boolean-expression*  
*Boolean-expression* = *Expression*

### Concrete syntax

<enabling condition> = <provided expression>  
 <provided expression>:: Boolean<expression>

### Mapping to abstract syntax

| <provided expression>( *expr*) **then** *Mapping*(*expr*)

#### F2.2.8.7 Save

### Abstract syntax

*Save-signalset* :: *Save-item-set*  
*Save-item* = *Signal-identifier* [ *Gate-identifier* ]

### Concrete syntax

<save part> :: [<virtuality>] <save list>  
 <save list> :: <save item>+ | <asterisk save list>  
 <asterisk save list> :: ()  
 <save item> :: <signal list item> [<via path>]

### Conditions on concrete syntax

$\forall s \in \langle \text{state} \rangle: |s.asteriskSaveListSet0| \leq 1$

A <state> is allowed to contain at most one <asterisk save list>. See clause 11.7 *Concrete grammar* of [ITU-T Z.103].

$\forall s \in \langle \text{state} \rangle: (s.asteriskInputListSet0 = \emptyset) \vee (s.asteriskSaveListSet0 = \emptyset)$

A <state> shall not contain both <asterisk input list> and <asterisk save list>. See clause 11.3 *Concrete grammar* of [ITU-T Z.103].

### Transformations

*sp* = <save part>( *virt*, <save list>( *a* = <asterisk save list>)) >  
**provided**  
*parentAS0ofKind*(*sp*, <state>).*s*-<state list>  $\notin$  <asterisk state list>  $\wedge$   
*parentAS0ofKind*(*sp*, <state>).*s*-<state list>.length = 1  
 =>

```

mk-<save part>(
  virt,
  mk-<save list>(<
    mk-<save item>( item , undefined) // signal list item, omitted via path
    : item ∈ ( explicitValidInputSigs0(parentASOfKind(sp,<agent type definition>)) \
      { sig ∈ <signal list item>:
        parentASOfKind(sig,<state>) = st ∧
        parentASOfKind(sp,<state>).s-<state list>.head in st.s-<state list> // same state
      } // set of signals in other inputs or saves of state
    >) // list of save items, save list
  ) // revised save part

```

An <asterisk save list> is transformed to a list of <stimulus>s containing the complete valid input signal set of the enclosing <agent definition>, except for <signal identifier>s of implicit input signals introduced by the concepts in clauses 10.5 and 10.6 of [ITU-T Z.102] and for <signal identifier>s contained in the other <input list>s and <save list>s of the <state>.

### Mapping to abstract syntax

```

| <save part>(*, svlist) then
  mk-Save-signalset({ Mapping(svlist.s-<save item>-seq[i] : i = 1..svlist.s-<save item>-seq.length )}

| <save item>( item, via) then mk-Save-item(Mapping(item.s-<signal list item>), Mapping(via) )

```

### Auxiliary functions

Get the set of <asterisk save list> for s <state>.

```

asteriskSaveListSet0(s: <state>): <asterisk save list>-set =def
  { asl ∈ <asterisk save list>: isAncestorAS0(s, asl) }

```

#### F2.2.8.8 Implicit transition

##### Transformations

The following statement is handled by the dynamic semantics.

Any signal not handled by an explicit input or save is consumed by an implicit transition (a transition of an implicit <input association area>) without a change of state.

#### F2.2.8.9 Spontaneous transition

##### Abstract syntax

```

Spontaneous-transition          ::      [ Provided-expression ]
                                   Transition

```

##### Concrete syntax

```

<spontaneous transition> ::
  [<virtuality>] [<enabling condition>] <transition>

```

##### Mapping to abstract syntax

```

| <spontaneous transition>(*, cond, trans) then
  mk-Spontaneous-transition(Mapping(cond), Mapping(trans))

```

#### F2.2.8.10 Label

##### Abstract syntax

```

Free-action                    ::      Connector-name Transition

```

##### Concrete syntax

```

<label> :: <connector name>

```

<connector name> = <name>

NOTE – An AS0 <connector name> is defined to be the same as an AS0 <name>, therefore the terms <connector name> and <connector><name> are interchangeable. In [ITU-T Z.101] a distinction is made between a <name> and an <integer name>, and a <connector name> can be either a <name> or an <integer name>.

<free action> :: <transition> [ <label> ]

### Conditions on concrete syntax

$\forall b \in \langle \text{composite state body} \rangle \cup \langle \text{operation body} \rangle \cup \langle \text{procedure body} \rangle \cup \langle \text{agent body} \rangle: \forall l, ll \in \langle \text{label} \rangle:$   
( $isAncestorAS0(b, l) \wedge isAncestorAS0(b, ll) \wedge (l \neq ll) \Rightarrow (l.s\text{-}\langle \text{name} \rangle \neq ll.s\text{-}\langle \text{name} \rangle)$ )

All the <connector><name>s defined in a body shall be distinct. See clause 11.10 *Concrete grammar* of [ITU-T Z.101].

$\forall fa \in \langle \text{free action} \rangle:$

**if**  $fa.s\text{-}\langle \text{transition action items} \rangle \neq \text{undefined} \wedge fa.s\text{-}\langle \text{transition action items} \rangle.s\text{-}\langle \text{action} \rangle\text{-seq} \neq \text{empty}$   
**then**  $fa.s\text{-}\langle \text{transition action items} \rangle.s\text{-}\langle \text{action} \rangle\text{-seq.head.s}\text{-}\langle \text{label} \rangle \neq \text{undefined} \wedge$   
 $fa.s\text{-}\langle \text{transition action items} \rangle.s\text{-}\langle \text{action} \rangle\text{-seq.head.s}\text{-}\langle \text{label} \rangle = fa.s\text{-}\langle \text{label} \rangle$   
**else**  $fa.s\text{-}\langle \text{terminator} \rangle \neq \text{undefined} \wedge fa.s\text{-}\langle \text{terminator} \rangle.s\text{-}\langle \text{label} \rangle \neq \text{undefined} \wedge$   
 $fa.s\text{-}\langle \text{terminator} \rangle.s\text{-}\langle \text{label} \rangle = fa.s\text{-}\langle \text{label} \rangle$   
**endif**

If the <transition string> of the <transition> in <free action> is non-empty, the first <action> shall have a <label> otherwise the <terminator> shall have a <label>. If present, the <label> ending the <free action> shall be the same as this <label>. See clause 5.7.9 of [ITU-T Z.106].

### Auxiliary functions

The function *getLabel* extracts the first label from the transition.

$getLabel(t: \langle \text{transition} \rangle): \langle \text{label} \rangle =_{\text{def}}$   
**if**  $t.s\text{-}\langle \text{action} \rangle = \text{empty}$  **then**  $t.s\text{-}\langle \text{terminator} \rangle.s\text{-}\langle \text{label} \rangle$   
**else**  $t.s\text{-}\langle \text{action} \rangle.head.s\text{-}\langle \text{label} \rangle$   
**endif**

### Transformations

$\langle \text{transition action items} \rangle (actions1 \hat{=} \langle la = \langle \text{action} \rangle(l, *) \rangle \hat{=} actions2, term = \langle \text{terminator} \rangle(tl, tn))$   
**provided**  $actions1 \neq \text{empty} \wedge l \neq \text{undefined}$   
 $=5 \Rightarrow$   
 $mk\text{-}\langle \text{transition action items} \rangle (actions1 \hat{=} mk\text{-}\langle \text{terminator} \rangle(\text{undefined}, mk\text{-}\langle \text{join} \rangle(l.s\text{-}\langle \text{name} \rangle))) \hat{=}$   
**if**  $actions2 \neq \text{empty}$  **then**  
 $mk\text{-}\langle \text{free action} \rangle (mk\text{-}\langle \text{transition action items} \rangle (\langle la \rangle \hat{=} actions2, term))$   
**elseif**  $term \neq \text{undefined}$  **then**  
**if**  $tl \neq \text{undefined}$  **then**  
 $mk\text{-}\langle \text{free action} \rangle (mk\text{-}\langle \text{transition action items} \rangle (\langle la \rangle \hat{=}$   
 $mk\text{-}\langle \text{terminator} \rangle(\text{undefined}, mk\text{-}\langle \text{join} \rangle(tl.s\text{-}\langle \text{name} \rangle))) \hat{=}$   
 $mk\text{-}\langle \text{free action} \rangle (term))$   
**else**  
 $mk\text{-}\langle \text{free action} \rangle (mk\text{-}\langle \text{transition action items} \rangle (\langle la \rangle \hat{=} mk\text{-}\langle \text{terminator} \rangle(l, tn)))$   
**endif**  
**endif**

$\langle \text{transition action items} \rangle (actions, term(tl, tn))$   
**provided**  $tl \neq \text{undefined}$   
 $=5 \Rightarrow$   
 $mk\text{-}\langle \text{transition action items} \rangle (actions \hat{=} mk\text{-}\langle \text{terminator} \rangle(\text{undefined}, mk\text{-}\langle \text{join} \rangle(tl.s\text{-}\langle \text{name} \rangle))) \hat{=}$   
 $mk\text{-}\langle \text{free action} \rangle (term)$

If a <label> is not the first label of a <transition string>, the <transition string> is split into two parts. All <action>s preceding the <label> are preserved in the original transition, which is terminated with a <join> to the <label>. All <action>s following <label> are copied to a new <free action>, which starts with the <label>. If the <transition string> is followed by a <terminator> with a label, the new <free action> is terminated with a <join> to the label of the <terminator> and another <free action> is made that contains the labelled <terminator>. If the <transition string> is followed by a <terminator> without a label, the new <free action> is terminated with the unlabelled <terminator>. If a <transition string> without any labels is followed by a labelled <terminator>, a <free action> is made that contains the labelled <terminator> and the <terminator> is replaced by a <join> to the label of the <terminator>. See clause 5.7.9 Model of [ITU-T Z.106].

## Mapping to abstract syntax

```
| <free action>(trans) then
  mk-Free-action(Mapping(getLabel(trans)), Mapping(trans))
```

### F2.2.8.11 State machine and composite state

#### Abstract syntax

<i>Composite-state-formal-parameter</i>	=	<i>Agent-formal-parameter</i>
<i>State-entry-point-definition</i>	=	<i>Name</i>
<i>State-exit-point-definition</i>	=	<i>Name</i>
<i>Exit-procedure-definition</i>	=	<i>Procedure-definition</i>
<i>Entry-procedure-definition</i>	=	<i>Procedure-definition</i>
<i>Named-start-node</i>	::	<i>State-entry-point-name</i> <i>Transition</i>

#### Conditions on abstract syntax

( $\forall d \in \text{Entry-procedure-definition}$ :  
 $(d.s\text{-Procedure-name} = \text{"entry"}) \wedge (d.\text{formalParameterList1} = \text{empty}) \wedge (d.\text{stateNodeSet1} = \emptyset)$ )

( $\forall d \in \text{Exit-procedure-definition}$ :  
 $(d.s\text{-Procedure-name} = \text{"exit"}) \wedge (d.\text{formalParameterList1} = \text{empty}) \wedge (d.\text{stateNodeSet1} = \emptyset)$ )

*Entry-procedure-definition* represents a procedure with the name entry. *Exit-procedure-definition* represents a procedure with the name exit. These procedures may not have parameters, and may only contain a single transition.

#### Concrete syntax

```
<composite state definition> ::
  <composite state graph> | <state aggregation>
```

#### Transformations

    ) // channel definition

```

The following paragraph is a general description copied from clause 9 *Model* of [ITU-T Z.103] and modified to apply to AS0.

A <composite state definition> is shorthand for a <composite state type definition> and it has a corresponding <state> or <composite state reference> or <state machine> referencing the <composite state definition>. A <state> or <state machine> that references the <composite state definition> contains a <composite state list item> with a <composite state name> that identifies the <composite state definition>. The <composite state list item> is transformed into a <typebased composite state> as described in clause 11.2 of [ITU-T Z.103]. Each <gate> of the transformed <state machine> identifies the anonymously named <textual gate definition> of the <composite state type> that corresponds to the set of channels connected to the original <state machine> at the same point. The identified channels all join the transformed <state machine> at the same <gate in definition> inside the <state machine>. A <composite state reference> that references a <composite state definition> is transformed as described in clause 9.5 of [ITU-T Z.103].

The following paragraphs are further description copied from clause 11.11.1 *Model* of [ITU-T Z.103] and modified to apply to AS0.

A <composite state definition> is shorthand for a <composite state type definition> transformed as described after the NOTE below. The corresponding reference references the <composite state definition> by its <state name> and is:

- a) a <state> with a <state list> item that is a <composite state list item>; or
- b) a <composite state reference> in a <state partition>; or
- c) a <state machine> with a <composite state list item>.

A corresponding <state> is shorthand for a <state> containing a <typebased composite state> that uses the <composite state type definition> (see also Note below). A corresponding <composite state

reference> is shorthand for a <textual typebased state partition def> (that is, a <typebased state partition heading>) that uses the <composite state type definition> (see also Note below). A corresponding <state machine> is shorthand for a <state> containing a <typebased composite state> that uses the <composite state type definition> (see also Note below).

NOTE – In the graphical grammar a corresponding <state area>, <composite state reference area> or <state machine area> is also shorthand for a <composite state type reference area> to the <composite state type diagram>, but in AS0 such a <composite state type reference> to the <composite state type definition> is not needed because the <composite state type definition> is created in the local scope.

If the composite state is not an aggregation, the <composite state type definition> is formed from the <composite state definition> by inserting the keyword **type** after the keyword **state** in the heading and changing the name to an anonymous name. The <composite state type heading> therefore has the <virtuality> given in the <composite state heading> of the <composite state definition>. The anonymous name is generated in the same way for redefinitions, so that the names match for the virtual type and redefinitions. The <composite state structure> is copied from the <composite state definition> to the <composite state type definition>. In the <composite state structure>, any part of a <qualifier> that refers to the composite state of the <composite state definition> is changed to refer to the composite state type of the <composite state type definition>. If the <composite state definition> is for a state machine, there is also a connected <gate in definition> for the composite state type definition with a unique anonymous name, for each channel attached to the <state machine area> for the <composite state definition>.

The model for a composite state that is an aggregation is described in clause 11.11.2 of [ITU-T Z.103] and is transformed in clause F2.2.8.11.2 below.

The transform for a composite state with only an asterisk state is in clause F2.2.8.11.1.

A <composite state definition> that has a specialization (with a <composite state heading> that contains a <specialization>) is shorthand for defining an implicit composite state type and one typebased composite state of this type.

A <procedure reference> is moved with the same <procedure reference heading> to the composite state type.

A <composite state type reference> is moved with the same <type preamble>, <qualifier>, <composite state type name> and <formal context parameters> to the composite state type.

### Auxiliary functions

The function *anonCompStateTypeName* is a mapping from composite state identities to names, used to store the name of the composite state type created from the transform of a <composite state definition> of a scope unit.

**controlled** *anonCompStateTypeName*: { *cs.fullIdentifier0*: *cs* ∈ <composite state definition> } → <name>  
**initially** ∇ *cs* ∈ <composite state definition> : *cs.fullIdentifier0* = *undefined*

The function *chanStateMachineGate* is a mapping from channel identities to names, used to store the name of the gate for channel connection. The gate is in composite state type from the transform of a <composite state definition>.

**controlled** *chanStateMachineGate*: { *cd.fullIdentifier0*: *cd* ∈ <channel definition> } → <name>  
**initially** ∇ *cd* ∈ <channel definition> : *cd.fullIdentifier0* = *undefined*

### F2.2.8.11.1 Composite state graph

#### Abstract syntax

*Composite-state-graph* :: *State-transition-graph*  
[ *Entry-procedure-definition* ]  
[ *Exit-procedure-definition* ]

## Concrete syntax

<composite state graph> ::  
    <package use clause>\* <composite state heading> <composite state structure>

<composite state heading> ::  
    <virtuality> [ <qualifier> ] <composite state name> [ <specialization> ] <agent formal parameters>

<composite state structure> ::  
    <state connection points>\* <entity in composite state>\*  
    <composite state body>

<entity in composite state> =  
    <valid input signal set>  
    | <variable definition>  
    | <data definition>  
    | <select definition>  
    | <procedure definition>  
    | <procedure reference>  
    | <composite state definition>  
    | <composite state type definition>  
    | <composite state type reference>  
    | <gate in definition>

<composite state body> ::  
    <start>\* { <state> | <free action> }\*

## Conditions on concrete syntax

$\forall csb \in \langle \text{composite state body} \rangle$ :  
 $\exists ! s \in \langle \text{start} \rangle: (s.parentAS0 = csb) \wedge (s.s\text{-name} = \text{undefined})$

At most, one of the <start>s shall be unlabelled. See clause 11.11.1 *Concrete grammar* of [ITU-T Z.102] modified with <start> replacing <start area>.

$\forall csd \in \langle \text{composite state definition} \rangle \cup \langle \text{composite state type definition} \rangle$ :  
 $(\forall pn \in \langle \text{name} \rangle: pn \in csd.usedEntryNameSet0 \Rightarrow pn \in csd.definedEntryNameSet0) \wedge$   
 $(\forall pn \in \langle \text{name} \rangle: pn \in csd.usedExitNameSet0 \Rightarrow pn \in csd.definedExitNameSet0)$

Each additional labelled entry and exit point shall be defined by a corresponding <state connection points>. See clause 11.11.1 *Concrete grammar* of [ITU-T Z.102] modified with <state connection points> replacing <state connection point area>.

$\forall csb \in \langle \text{composite state body} \rangle$ :  
 $(s1 \in \langle \text{start} \rangle \wedge s1.parentAS0 = csb \wedge s1.s\text{-name} \neq \text{undefined}) // s1 \text{ labelled start of composite state}$   
 $\wedge$   
 $(s2 \in \langle \text{start} \rangle \wedge s2.parentAS0 = csb \wedge s2.s\text{-name} \neq \text{undefined}) // s2 \text{ labelled start of composite state}$   
 $\Rightarrow$   
 $((s1 = s2) \vee (s1.s\text{-name} \neq s2.s\text{-name}))$

Each additional labelled <start> shall contain a different <state entry point<name>. See clause 11.11.1 *Concrete grammar* of [ITU-T Z.102] modified with <start> replacing <start area>.

$\forall csb \in \langle \text{composite state body} \rangle$ :  
 $(\forall s \in \{ \langle \text{start} \rangle \wedge s.parentAS0 = csb \wedge s.s\text{-name} \neq \text{undefined} \} // s \text{ labelled start of composite state body})$ :  
 $(s.s\text{-name} \in \{ \text{sepname} : \text{sepname in } csb.parentAS0.s\text{-state connection points}\text{-seq}.s\text{-state entry points}\text{-seq} \})$

A <start> with a <state entry point<name> (a labelled start) in a <composite state body> shall refer only to <state entry point>s of the <composite state type graph> directly enclosing the <composite state body>. See clause 11.11.1 *Concrete grammar* of [ITU-T Z.102] modified with <start> replacing <start area>, <composite state body> replacing <composite state body area> and <composite state type graph> replacing <composite state type diagram>.

$\forall csb \in \langle \text{composite state body} \rangle$ :  
 $(\forall r \in \{ \langle \text{return} \rangle \wedge r.parentAS0 = csb \wedge r.s\text{-name} \neq \text{undefined} \} // r \text{ labelled return composite state body})$

$(r.s\text{-}\langle\text{name}\rangle \in \{ \text{epname} : \text{epname in } \text{csb.parentAS0.s}\text{-}\langle\text{state connection points}\rangle\text{-seq.s}\text{-}\langle\text{state exit points}\rangle\text{-seq} \})$

A  $\langle\text{return area}\rangle$  with a  $\langle\text{state exit point}\rangle$  (a labelled return) in a  $\langle\text{composite state body area}\rangle$  shall refer only to  $\langle\text{state exit point}\rangle$ s in the  $\langle\text{composite state type graph}\rangle$  directly enclosing the  $\langle\text{composite state body}\rangle$ . See clause 11.11.1 *Concrete grammar* of [ITU-T Z.102] modified with  $\langle\text{return}\rangle$  replacing  $\langle\text{return area}\rangle$ ,  $\langle\text{composite state body}\rangle$  replacing  $\langle\text{composite state body area}\rangle$  and  $\langle\text{composite state type graph}\rangle$  replacing  $\langle\text{composite state type diagram}\rangle$ .

$\forall \text{csb} \in \langle\text{composite state body}\rangle: \forall s \in \langle\text{state}\rangle: (s \in \text{csb.surroundingScopeUnit0.stateSet0}) \wedge ((s.s\text{-}\langle\text{state list}\rangle \notin \langle\text{asterisk state list}\rangle) \Rightarrow \text{csg.surroundingScopeUnit0.startSet0} \neq \emptyset)$

If a  $\langle\text{composite state body}\rangle$  contains at least one  $\langle\text{state}\rangle$ , a  $\langle\text{start}\rangle$  shall be present. See clause 11.11.1 *Concrete grammar* of [ITU-T Z.102] modified with  $\langle\text{state}\rangle$  replacing  $\langle\text{state area}\rangle$ , and  $\langle\text{composite state body}\rangle$  replacing  $\langle\text{composite state body area}\rangle$ .

$\forall \text{cst} \in \langle\text{composite state type definition}\rangle: \forall \text{vd} \in \langle\text{variable definition}\rangle: (\text{vd.surroundingScopeUnit0} = \text{cst}) \wedge (\text{cs.surroundingScopeUnit0} \in \langle\text{internal procedure definition}\rangle) \Rightarrow (\text{vd.s-exported} = \text{undefined})$

$\langle\text{variable definition}\rangle$  in an  $\langle\text{entity in composite state}\rangle$ , shall not contain **exported**  $\langle\text{variable}\rangle\langle\text{name}\rangle$ s, if the  $\langle\text{composite state type definition}\rangle$  is enclosed by an  $\langle\text{internal procedure definition}\rangle$ . See clause 11.11.1 *Concrete grammar* of [ITU-T Z.102] modified with  $\langle\text{entity in composite state}\rangle$  replacing  $\langle\text{composite state text area}\rangle$ ,  $\langle\text{composite state type definition}\rangle$  replacing  $\langle\text{composite state type diagram}\rangle$ , and  $\langle\text{internal procedure definition}\rangle$  replacing  $\langle\text{procedure diagram}\rangle$ .

## F2.2.8.11.2 State aggregation

### Abstract syntax

<i>State-aggregation-node</i>	::	<i>State-partition-set</i> [ <i>Entry-procedure-definition</i> ] [ <i>Exit-procedure-definition</i> ]
<i>State-partition</i>	::	<i>Name</i> <i>Composite-state-type-identifier</i> <i>Connection-definition-set</i>
<i>Connection-definition</i>	=	<i>Entry-connection-definition</i>   <i>Exit-connection-definition</i>
<i>Entry-connection-definition</i>	::	<i>Outer-entry-point</i> <i>Inner-entry-point</i>
<i>Outer-entry-point</i>	::	<i>State-entry-point-name</i>
<i>Inner-entry-point</i>	::	<i>Nextstate-parameters</i>
<i>Exit-connection-definition</i>	::	<i>Outer-exit-point</i> <i>Inner-exit-point</i>
<i>Outer-exit-point</i>	::	<i>State-exit-point-name</i>
<i>Inner-exit-point</i>	::	<i>State-exit-point-name</i>

### Conditions on abstract syntax

See clause 11.11.2 *Abstract grammar* of [ITU-T Z.102].

$$\forall pn \in \text{State-entry-point-name}: (pn.\text{parentAS1} \in \text{Outer-entry-point}) \Rightarrow (pn \in pn.\text{surroundingScopeUnit0}.\text{entryPointSet1}) \wedge (pn.\text{surroundingScopeUnit0}.\text{s-implicit} \in \text{State-aggregation-node})$$

The *State-entry-point-name* in the *Outer-entry-point* shall denote a *State-entry-point-definition* of the *Composite-state-type-definition* where the *State-aggregation-node* occurs.

$$\forall pn \in \text{State-entry-point-name}: (pn.\text{parentAS1} \in \text{Inner-entry-point}) \Rightarrow (pn \in \text{parentAS1ofKind}(pn, \text{State-partition}).\text{baseType1}.\text{entryPointSet1})$$

The *State-entry-point-name* of the *Inner-entry-point* shall denote a *State-entry-point-definition* of the composite state in the *State-partition*.

$$\forall pn \in \text{State-exit-point-name}: (pn.\text{parentAS1} \in \text{Outer-exit-point}) \Rightarrow \\ (pn \in pn.\text{surroundingScopeUnit0}.\text{exitPointSet1}) \wedge \\ (pn.\text{surroundingScopeUnit0}.\text{s-implicit} \in \text{State-aggregation-node})$$

The *State-exit-point-name* of the *Outer-exit-point* shall denote a *State-exit-point-definition* of the *Composite-state-type-definition* where the *State-aggregation-node* occurs.

$$\forall pn \in \text{State-exit-point-name}: (pn.\text{parentAS1} \in \text{Inner-exit-point}) \Rightarrow \\ (pn \in \text{parentAS1ofKind}(pn, \text{State-partition}).\text{baseType1}.\text{exitPointSet1})$$

The *State-exit-point-name* of the *Inner-exit-point* shall denote a *State-entry-point-definition* of the composite state in the *State-partition*.

$$\forall td \in \text{Composite-state-type-definition}: (td.\text{s-implicit} \in \text{State-aggregation-node}) \Rightarrow \\ \exists ! cd \in \text{Connection-definition}: (cd.\text{surroundingScopeUnit0} = td) \wedge \\ (\text{let } \text{pointSet} = \{pn \in \text{State-entry-point-definition} \cup \text{State-exit-point-definition}: \\ (pn \in td.\text{entryPointSet1} \cup td.\text{exitPointSet1}) \vee \\ (\exists sp \in \text{State-partition}: (sp.\text{surroundingScopeUnit0} = td) \wedge \\ (pn \in sp.\text{baseType1}.\text{entryPointSet1} \cup sp.\text{baseType1}.\text{exitPointSet1}))\} \\ \text{in} \\ \text{let } \text{pointSet1} = \\ \{pn \in \text{State-entry-point-definition} \cup \text{State-exit-point-definition}: \text{isAncestorAS1}(cd, pn)\} \\ \text{in} \\ \text{pointSet} \subseteq \text{pointSet1} \\ \text{endlet } // \text{pointSet1} \\ \text{endlet } // \text{pointSet} \\ )$$

For each *State-partition*, each of the entry points of the container state shall appear in exactly one *Connection-definition*. For each *State-partition*, each of the exit points of the *State-partition* shall appear in exactly one *Connection-definition*.

$$\forall sp, sp1 \in \text{State-partition}: (sp \neq sp1) \wedge (sp.\text{parentAS1} = sp1.\text{parentAS1}) \Rightarrow \\ sp.\text{inputSignalSet1} \cap sp1.\text{inputSignalSet1} = \emptyset$$

The input signal sets of the *State-partition* items within a composite state shall be disjoint.

## Concrete syntax

```
<state aggregation> ::
    <package use clause>* <state aggregation heading> <aggregation structure>

<state aggregation heading> =
    <composite state heading>

<aggregation structure> ::
    { <state connection points> | <entity in state aggregation> }*
    <state aggregation body>

<state aggregation body> = { <state partition> | <state partition connection> }*

<state partition connection> = <state partition connection entry>
    | <state partition connection exit>

<state partition connection entry> ::
    [ <composite state<identifier> ] <outer entry points>
    <composite state<identifier> <inner entry point>

<outer entry points> :: <state entry point>+ | default

<inner entry point> :: <nextstate parameters> | <state entry point> | default

<state entry point> = <state entry point<name>

<state partition connection exit> ::
    [ <composite state<identifier> ] <outer exit point>
    <composite state<identifier> <inner exit points>

<outer exit point> :: <state exit point> | default
```

```

<inner exit points> :: <state exit points> | default
<state partition> =
  <textual typebased state partition def> | <composite state reference> | <composite state definition>
<entity in state aggregation> =
  <valid input signal set>
  | <variable definition>
  | <data definition>
  | <select definition>
  | <procedure definition>
  | <procedure reference>
  | <composite state type definition>
  | <composite state type reference>
  | <gate in definition>

```

## Transformations

NOTE – The allocation of an anonymous name for the composite state and transform of references is the same for a composite state graph and a state aggregation, and is defined in the first transform (and its dependent transforms) in clause F2.2.8.11.

```

cs = <composite state definition>(
  // transform <composite state definition> cs to <composite state type definition>
  graph = <state aggregation>(uses, // package uses
    hdg = <composite state heading>(virt, // virtuality
      qual // qualifier – should be undefined = defined in context
      name, // name
      special, // specialization
      params // agent formal parameters
    ), // composite state heading (alias state aggregation heading)
    structure
  ) // state aggregation
) // composite state
provided
cs.fullIdentifier0.anonCompStateTypeName ≠ undefined ∧
((∃ sm ∈ <composite state list item>:
  (sm.parentAS0 ∈ <interaction> ∧ // composite state list item that is a state machine
    sm.surroundingScopeUnit0 = cs.surroundingScopeUnit0 ∧ //same scope as cs
    sm.s-<name> = //same name as composite state
    cs.s-<composite state graph>.s-<composite state heading>.s-<name>)
  )
⇒ // for a state machine, the gate name for a channel
(∃ cd ∈ <channel definition>: // channel with defined gate in state machine
  (chanStateMachineGate( cd.fullIdentifier0 ) ≠ undefined ∧
    ( cd.s-<channel path>.s1-<channel endpoint>.refersto0 = cs ∨
      cd.s-<channel path>.s2-<channel endpoint>.refersto0 = cs ))
  ))
=12=>
mk-<composite state type definition>(
  mk-<state aggregation type>( uses, // package uses
    mk-<state aggregation type heading>( virt, // virtuality
      qual // qualifier – should be undefined = defined in context
      cs.fullIdentifier0.anonCompStateTypeName, // anonymous name
      undefined, // formal context parameters
      undefined, // virtuality constraint
      special, // specialization
      params // agent formal parameters
    ), // state aggregation type heading
    structure
  ) // state aggregation type
) // composite state type definition

```

The <composite state type definition> for the aggregation is formed from the <composite state definition> by changing the <state aggregation> into a <state aggregation type> by inserting the keyword **type** after the keyword **aggregation** in the heading and changing the name to an anonymous name. The <state aggregation type heading> therefore has the <virtuality> given in the <state aggregation heading> of the <composite state definition>. The anonymous name is generated in the same way for redefinitions, so that the names match for the virtual type and redefinitions. The <aggregation structure> is copied from the <composite state definition> to the <composite state type definition>. In the <composite state structure>, any part of a <qualifier> that refers to the composite state of the <composite state definition> is changed to refer to the composite state type of the <composite state type definition>. Modified text from clause 11.11.2 *Model* of [ITU-T Z.103].

*The following paragraph (see clause 11.11.2 Semantics of [ITU-T Z.102]) is formalized by the dynamic semantics.*

If there are signals in the complete valid input set of the *Composite-state-type-definition* where a *State-aggregation-node* occurs that are not consumed by any *State-partition* of the *State-aggregation-node*, there is an implied additional *State-partition*. The implied *Composite-state-type-definition* for this *State-partition* has a *Composite-state-graph* that is a *State-transition-graph* with a single unlabelled *State-start-node* with a transition to a single *State-node*. This *State-node* has an *Input-node* for each signal handled (including those for exported procedures and exported variables) and a *Continuous-signal*. The *Transition* of each *Input-node* is an empty transition back to the state. The *Continuous-signal* has a *Continuous-expression* that is a logical 'and' that accesses implicit Boolean variables, one for each (non-implicit) partition. These variables are shared by all partitions and each initialized to False. When each of the other partitions has interpreted either an *Action-return-node* or *Named-return-node*, its implicit Boolean variable is set to True. The *Transition* of the *Continuous-signal* contains just an *Action-return-node*. Therefore, when other partitions have completed, and the additional partition has consumed all the signals for it (if any) in the input port, the partition exits through an *Action-return-node*. See clause 11.11.2 *Semantics* of [ITU-T Z.102].

## Auxiliary functions

Get the set of input signals appearing in a type definition, a state partition or a state node.

```
inputSignalSet1(sp: TYPEDEFINITION1 ∪ State-partition ∪ State-node): SIGNAL1 =def
  if sp ∈ State-node then
    sp.s-Save-signalset ∪ { in.s-Signal-identifier | in ∈ sp.s-Input-node-set } ∪
    { getEntityDefinition1(cn.s-Procedure-identifier, procedure).inputSignalSet1 |
      cn ∈ { cn ∈ Call-node: isAncestorAS1(sp, cn) } }
  else // sp ∈ TYPEDEFINITION1 ∪ State-partition
    { sn.inputSignalSet1 | sn ∈ sp.stateNodeSet1 }
  endif
```

Get the base type of a definition.

```
baseType1(as:
  Agent-definition ∪ Composite-state-type-definition ∪ State-machine ∪ State-partition ∪ State-node):
  Agent-type-definition ∪ Composite-state-type-definition =def
  case as of
  | Agent-definition then
    if as.s-Agent-type-identifier = undefined
    then undefined
    else getEntityDefinition1(as.s-Agent-type-identifier, agent type)
    endif
  | Composite-state-type-definition ∪ State-machine ∪ State-partition ∪ State-node then
    if as.s-Composite-state-type-identifier = undefined
    then undefined
    else getEntityDefinition1(as.s-Composite-state-type-identifier, state type)
    endif
  otherwise undefined
```

**endcase**

Get the set of the state entry points of a *Composite-state-type-definition*.

*entryPointSet1(d: Composite-state-type-definition): Name-set* =<sub>def</sub>  
*d.s-State-entry-point-definition-set*

Get the set of the state exit points of a *Composite-state-type-definition*.

*exitPointSet1(d: Composite-state-type-definition): Name-set* =<sub>def</sub>  
*d.s-State-exit-point-definition-set*

## Mapping to abstract syntax

```
| <state partition connection entry>( <outer entry points>( n1 ), <inner entry point>( n2 )) then
let innerEntryPoint =
  mk-Inner-entry-point(
    case n2 of
    | <nextstate parameters> then Mapping(n2)
    | <state entry point> then mk-Nextstate-parameters(empty, Mapping(n2))
    otherwise // default
      mk-Nextstate-parameters(empty, Mapping(newName))
    endcase
  )
in
if n1 = default
then { mk-Entry-connection-definition(Mapping(newName), innerEntryPoint) }
else // n1 = state entry point list
  { mk-Entry-connection-definition(
    mk-Outer-entry-point(n1[i]),
    innerEntryPoint
    : i ∈ 1.. n1.length
  )
  }
endif
endlet // innerEntryPoint

| <state partition connection exit>( <outer exit point>( n1 ), <inner exit points>( n2 )) then
let outerExitPoint =
  mk-Outer-exit-point(
    case n1 of
    | <state exit point> then Mapping(n1)
    otherwise // default
      Mapping(newName)
    endcase
  )
in
if n2 = default
then { mk-Exit-connection-definition(outerExitPoint, Mapping(newName)) }
else // n2 = state exit point list
  { mk-Exit-connection-definition(
    outerExitPoint,
    mk-Inner-exit-point(Mapping(n2[i]))
    : i ∈ 1.. n2.length
  )
  }
endif
endlet // outerExitPoint
```

### F2.2.8.11.3 State connection point

#### Concrete syntax

<state connection points> = <state entry points> | <state exit points>  
<state entry points> :: <state entry point>+

<state exit points> :: <state exit point>+  
 <state exit point> = <state exit point<name>

## Mapping to abstract syntax

| <state entry points>(x) **then** Mapping(x)  
 | <state exit points>(x) **then** Mapping(x)

### F2.2.8.11.4 Connect

#### Abstract syntax

Connect-node :: [ State-exit-point-name ] Transition

#### Conditions on abstract syntax

$\forall sn \in \text{State-node}: \forall cn, cn1 \in \text{Connect-node}:$   
 $(cn \neq cn1) \wedge (cn.\text{parentAS1} = sn) \wedge (cn1.\text{parentAS1} = sn) \Rightarrow$   
 $cn.\text{s-State-exit-point-name} \neq cn1.\text{s-State-exit-point-name}$

The *Connect-node-set* shall contain at most one unnamed *Connect-node*. See clause 11.2 of [ITU-T Z.101].

Each *Connect-node* in the *Connect-node-set* of a composite state application shall either be the only *Connect-node* without a *State-exit-point-name* or have a *State-exit-point-name* that is different from every other *Connect-node* in the *Connect-node-set*. See clause 11.2 of [ITU-T Z.102].

#### Concrete syntax

<connect part> ::  
 [<virtuality>] <connect list> <exit transition>  
 <exit transition> = <transition>  
 <connect list> = <state exit point list> | <asterisk connect list>  
 <state exit point list> = <state exit point<name>\*  
 <asterisk connect list> :: ()

#### Transformations

```
< <connect part>(virt, connectList, trans) >
provided connectList  $\notin$  <asterisk connect list>  $\wedge$  connectList.length > 1
=8=>
< mk-<connect part>(virt, < connectList.head >, trans) > ^
  if connectList.length > 1 then mk-<connect part>(virt, connectList.tail, trans) else empty endif
>
```

When the <connect list> of a certain <connect part> contains more than one <state exit point>, a copy of the <connect part> is created for each such <state exit point>. Then the <connect part> is replaced by these copies. See clause 11.11.4 *Model* of [ITU-T Z.103].

```
c=<connect part>(virt, <asterisk connect list>, trans)
=8=>
( let parentType = c.parentAS0.s-<state list>.head.s-<type expression>.refersto0 in
  let allExits = bigSeq(< ex.s-<name> | ex in exits > |
    exits in parentType.s-<composite state structure>.s-<state connection points>-seq:
      (exits  $\in$  <state exit points>) >)
  in
    mk-<connect part>(virt, allExits, trans)
  endlet // allExits
  endlet // parentType
)
```

A <connect list> that contains an <asterisk connect list> is transformed into a list of <state exit point>s, one for each <state exit point> of the <composite state definition> in question. The list of <state exit point>s is then transformed as described above. See clause 11.11.4 *Model* of [ITU-T Z.103].

## Mapping to abstract syntax

| <connect part>(\*, < name >, trans) **then**  
     **mk-Connect-node**(Mapping(name), Mapping(trans))

### F2.2.8.12 Transition

#### F2.2.8.12.1 Transition body

##### Abstract syntax

<i>Transition</i>	::	<i>Graph-node</i> * { <i>Terminator</i>   <i>Decision-node</i> }
<i>Graph-node</i>	::	{ <i>Task-node</i>   <i>Output-node</i>   <i>Create-request-node</i>   <i>Call-node</i>   <i>Compound-node</i>   <i>Set-node</i>   <i>Reset-node</i> }
<i>Terminator</i>	::	{ <i>Nextstate-node</i>   <i>Stop-node</i>   <i>Return-node</i>   <i>Join-node</i>   <i>Continue-node</i>   <i>Break-node</i> }

##### Concrete syntax

<transition> = <transition action items> | <terminator>  
 <transition action items> :: <transition string> [<terminator>]  
 <transition string> = <action>+  
 <action> :: [<label>] <action item>  
 <action item> =  
     <task>  
     | <output>  
     | <create request>  
     | <decision>  
     | <set>  
     | <reset>  
     | <export statement>  
     | <procedure call>  
     | <remote procedure call>  
     | <transition option>  
 <terminator> :: [<label>] <terminator node>  
 <terminator node> = <nextstate> | <join> | <stop> | <return>

##### Conditions on concrete syntax

$\forall t \in \langle \text{transition} \rangle: (t \notin \langle \text{terminator} \rangle) \wedge (t.s - \langle \text{terminator} \rangle = \text{undefined}) \wedge$   
 $(t.\text{parentAS0}.\text{parentAS0}.\text{parentAS0} \notin \langle \text{decision} \rangle \cup \langle \text{transition option} \rangle) \Rightarrow$   
     **(let** *asl* = *t.s* - <action> - **seq in**  
         (*asl.last.s* - <action item>  $\in \langle \text{decision} \rangle \cup \langle \text{transition option} \rangle$ )  $\wedge$   
         *isTransitionTerminating0*(*asl.last* - <action item>) **endlet**)

endlet)

If the <terminator> of a <transition> is omitted, then the last action in the <transition> shall contain a terminating <decision> or terminating <transition option>, except when a <transition> is contained in a <decision> or <transition option>. See clause 5.7.11.1 of [ITU-T Z.106].

## Transformations

The following transformation is handled in the transformations for remote procedure call and import expression.

A transition action may be transformed to a list of actions (possibly containing implicit states) according to the transformation rules for <import expression> and <remote procedure call>.

## Mapping to abstract syntax

```
| <transition action items>(s, t) then  
  if t = undefined  
  then mk-Transition(Mapping(<s[i]: i=1..s.length-1 ∧ (s[i] ∉ <decision>) >), Mapping(s.last))  
  else mk-Transition(Mapping(s), Mapping(t))  
  endif  
  
| <action>(*, a) then Mapping(a)  
  
| <terminator>(l, t) then  
  if l ≠ undefined  
  then mk-Free-action(Mapping(l), mk-Transition(empty, Mapping(t)))  
  else mk-Transition(empty, Mapping(t))  
  endif
```

## Auxiliary functions

The function *isTransitionTerminating0* determines if a <decision> or a <transition option> is terminating.

```
isTransitionTerminating0(dt: <decision> ∪ <transition option>): BOOLEAN =def  
  ∀ t ∈ <transition>: (t.parentAS0.parentAS0.parentAS0 = dt) ⇒  
    ((t ∈ <terminator>) ∨  
     ((t ∉ <terminator>) ∧ (t.s-<terminator> ≠ undefined)) ∨  
     ((t ∉ <terminator>) ∧ (t.s-<terminator> = undefined) ∧  
      isTransitionTerminating0(t.s-<action>-seq.last.<action item>)))
```

### F2.2.8.12.2 Nextstate

#### Abstract syntax

```
Nextstate-node           =   Named-nextstate | Dash-nextstate  
Dash-nextstate          ::   [ HISTORY ]  
Named-nextstate         ::   State-name [ Nextstate-parameters ]  
Nextstate-parameters   ::   Actual-parameters  
                        [ State-entry-point-name ]
```

#### Conditions on abstract syntax

```
∀ nn ∈ Named-nextstate: ( nn.s-Name ∈  
  { sn.s-Name : sn ∈ parentAS1ofKind(nn, State-transition-graph ∪ Procedure-graph).s-State-node-set)
```

The *State-name* specified in a nextstate shall be the name of a state within the same *State-transition-graph* or *Procedure-graph*. See clause 11.12.2.1 *Abstract grammar* of [ITU-T Z.101].

```
∀ tn ∈ { Transition: tn.s-Terminator.s-Nextstate-node ∈ Dash-nextstate } // tn terminates in Dash-nextstate  
isTransitionFromState1(tn)
```

Every *Transition* that terminates in a *Dash-nextstate* shall originate from a *State-node* within the same *State-transition-graph* or *Procedure-graph*, either directly or via *Decision-node* items or *Join-node* items and *Free-action* items. See clause 11.12.2.1 *Abstract grammar* of [ITU-T Z.101].

NOTE – The purpose of the condition above is to check that the *Transition* originates from a *State-node* and not from a *State-start-node* or a *Named-start-node* or a *Procedure-start-node*.

$$\begin{aligned} & \forall nn \in \text{Named-nextstate}: nn.\mathbf{s}\text{-Nextstate-parameters} \neq \text{undefined} \\ \Rightarrow & \\ & ( \quad sn \in \text{parentAS1ofKind}(nn, \text{State-transition-graph} \cup \text{Procedure-graph}).\mathbf{s}\text{-State-node-set} \\ & \wedge \quad nn.\mathbf{s}\text{-Name} = sn.\mathbf{s}\text{-Name} \\ & \wedge \quad sn.\mathbf{s}\text{-Composite-state-type-identifier} \neq \text{undefined} \\ & \wedge \quad \text{getEntityDefinition1}(sn.\mathbf{s}\text{-Composite-state-type-identifier}, \\ & \quad \quad \quad \mathbf{state\ type}).\mathbf{s}\text{-Composite-state-formal-parameter-seq.length} \\ & \quad \quad \quad = nn.\mathbf{s}\text{-Nextstate-parameters}.\mathbf{s}\text{-Actual-parameters.length} \\ & \wedge \quad (\forall i \in 1.. nn.\mathbf{s}\text{-Nextstate-parameters}.\mathbf{s}\text{-Actual-parameters.length}): \\ & \quad ( \quad (nn.\mathbf{s}\text{-Nextstate-parameters}.\mathbf{s}\text{-Actual-parameters}[i] = \text{UNDEFINED}) \\ & \quad \quad \vee \quad \text{isCompatibleTo1}(nn.\mathbf{s}\text{-Nextstate-parameters}.\mathbf{s}\text{-Actual-parameters}[i].\text{staticSort1}, \\ & \quad \quad \quad \text{getEntityDefinition1}(sn.\mathbf{s}\text{-Composite-state-type-identifier}, \\ & \quad \quad \quad \quad \quad \quad \mathbf{state\ type}).\mathbf{s}\text{-Composite-state-formal-parameter-seq}[i].\text{staticSort1} \\ & \quad \quad ) \quad ) \\ & ) \end{aligned}$$

If a *Named-nextstate* includes *Nextstate-parameters*, the *State-name* shall refer to a composite state (a *State-node* with a *Composite-state-type-identifier*). In that case, the *Actual-parameters* shall have the same number of elements as the *Composite-state-formal-parameter* list of the identified *Composite-state-type-definition*. Each *Expression of the Actual-parameters* shall have a sort that is compatible with the sort of the corresponding by position *Composite-state-formal-parameter* in the *Composite-state-type-definition*. See clause 11.12.2.1 *Abstract grammar* of [ITU-T Z.101].

### Concrete syntax

```
<nextstate> = <nextstate body>
<nextstate body> = <nextstate body name> | <dash nextstate> | <history dash nextstate>
<nextstate body name> ::
    <basic state<name>
    | <composite state<name> <nextstate parameters>
<nextstate parameters> :: <actual parameters> [ <state entry point<name> ]
<dash nextstate> :: ()
<history dash nextstate> :: ()
```

### Mapping to abstract syntax

```
| <nextstate body name>( sn, nspars ) then
    mk-Terminator(mk-Named-nextstate(Mapping(sn), Mapping(nspars)))

| <nextstate parameters>( params ) then mk-Nextstate-parameters(Mapping(params))

| <nextstate parameters>( params, n ) then mk-Nextstate-parameters(Mapping(params), Mapping(n))

| <dash nextstate>() then mk-Terminator(mk-Dash-nextstate(undefined))

| <history dash nextstate>() then mk-Terminator(mk-Dash-nextstate(HISTORY))
```

### Auxiliary functions

The function *isTransitionFromState1* determines if a *Transition* originates (directly or indirectly) from a *State-node*.

*isTransitionFromState1*(tn: *Transition*): *BOOLEAN* =<sub>def</sub>

```

case m.parentASI of
| Input-node ∪ Continuous-signal ∪ Spontaneous-transition ∪ Connect-node ∪ State-timer then true
| State-start-node ∪ Named-start-node ∪ Procedure-start-node then false
| Decision-answer ∪ Else-answer ∪ Any-decision then
  isTransitionFromState1(parentASIofKind(m.parentASI, Decision-node).parentASI)
  // call recursively with transition containing decision node containing answer, else or any
| Free-action then
  ¬ (∃ jn ∈ Join-node : (jn.s-Name = m.parentASI.s-Name //connector names same in join and free action
  ∧ parentASIofKind(m, State-transition-graph ∪ Procedure-graph) =
    parentASIofKind(jn, State-transition-graph ∪ Procedure-graph) // in same graph
  ∧ isTransitionFromState1(jn.parentASI.parentASI) = false
    // call recursively with transition containing terminator that is parent of join
  ))
// The Terminator of a Compound-node is never a nextstate.
otherwise false
endcase

```

### F2.2.8.12.3 Join

#### Abstract syntax

*Join-node* :: *Connector-name*

#### Concrete syntax

<join> :: <connector><name>

#### Conditions on concrete syntax

$\forall b \in \langle \text{agent body} \rangle \cup \langle \text{procedure body} \rangle \cup \langle \text{operation body} \rangle \cup \langle \text{composite state body} \rangle :$   
 $\forall j \in \langle \text{join} \rangle : \text{isAncestorAS0}(b, j) \Rightarrow$   
 $(\exists ! l \in \langle \text{label} \rangle : \text{isAncestorAS0}(b, l) \wedge (j.s\text{-}\langle \text{name} \rangle = l.s\text{-}\langle \text{name} \rangle))$

There shall be exactly one <connector><name> corresponding to a <join> within the same body. See clause 5.7.11.2.2 of [ITU-T Z.106].

#### Mapping to abstract syntax

| <join>(name) **then** *mk-Terminator(mk-Join-node(Mapping(name)))*

### F2.2.8.12.4 Stop

#### Abstract syntax

*Stop-node* :: ()

#### Conditions on abstract syntax

#### Concrete syntax

<stop>:: ()

#### Mapping to abstract syntax

| <stop>() **then** *mk-Terminator(mk-Stop-node())*

### F2.2.8.12.5 Return

#### Abstract syntax

*Return-node* = *Action-return-node*  
| *Value-return-node*  
| *Named-return-node*  
  
*Action-return-node* :: ()  
  
*Value-return-node* :: *Expression*

*Named-return-node* :: *State-exit-point-name*

## Conditions on abstract syntax

$\forall rn \in \text{Action-return-node}$ :  
(  $(\exists pd \in \text{Procedure-definition} : (\text{isAncestorASI}(pd.s\text{-Procedure-graph}, rn) \wedge pd.s\text{-Result} = \text{undefined}))$   
 $\vee$  (  $(\exists cstg \in \text{Composite-state-graph} : (\text{isAncestorASI}(cstg, rn))$   
     $\wedge \neg(\exists pd \in \text{Procedure-definition} : (\text{isAncestorASI}(pd.s\text{-Procedure-graph}, rn) \wedge pd.s\text{-Result} \neq \text{undefined}))$   
    )  
)

An *Action-return-node* shall only be contained in the *Procedure-graph* of a *Procedure-definition* without *Result* or a *Composite-state-graph*. See clause 11.12.2.4 *Abstract grammar* of [ITU-T Z.101].

$\forall rn \in \text{Value-return-node}$ :  $(\exists d \in \text{Procedure-definition}$ :  
     $(\text{isAncestorASI}(d.s\text{-Procedure-graph}, rn) \wedge d.s\text{-Result} \neq \text{undefined}))$

A *Value-return-node* shall only be contained in the *Procedure-graph* of a *Procedure-definition* containing *Result*. See clause 11.12.2.4 *Abstract grammar* of [ITU-T Z.101].

$\forall rn \in \text{Named-return-node}$ :  
( $\exists sg \in \text{Composite-state-graph}$ :  
    ( *parentASIofKind*(*rn*, *sg*)  
     $\wedge cstd = sg.parentASI$  // Composite-state-type-definition parent of *sg*  
     $\wedge sepdef \in sg.parentASI.s4$  // sepdef member of State-exit-point-definition-set of *cstd*  
     $\wedge rn.s\text{-Name} = sepdef$  // Name matches State-exit-point-definition  
    ) )

A *Named-return-node* shall be directly contained in a *Composite-state-graph* that has a *State-exit-point-definition* with the same *Name* as the *State-exit-point-name*. See clause 11.12.2.4 *Abstract grammar* of [ITU-T Z.102].

## Concrete syntax

`<return> :: <return body> | <state exit point><name>`  
`<return body> :: [<expression>]`

## Mapping to abstract syntax

```
| <return>(x) then
  if x = undefined
  then mk-Terminator(mk-Action-return-node())
  elseif x in <name> // then it is a state exit name, otherwise it is a <return body>
  then mk-Terminator(mk-Named-return-node(Mapping(x))) // state exit name
  else mk-Terminator(mk-Value-return-node(Mapping(x))) // expression
endif
```

### F2.2.8.13 Action

#### F2.2.8.13.1 Task

##### Abstract syntax

*Task-node* = *Assignment*  
| *Informal-text*

##### Concrete syntax

`<task> :: { <task body> | <informal text> | <legacy task body> }`  
`<task body> :: <variable definitions> <statements>`  
`<legacy task body> = <assignment>+`

## Transformations

```
< <task>( <task body>( vl, sl )) >
=3=> < mk-<compound statement>( undefined, vl, sl ) >
```

Each <non terminating statement> of <task body> of a <task> represents an element of the *Graph-node* list for the *Transition* of the <transition> containing the <task> in the order that each <non terminating statement> occurs in the <task>. See clause 11.13.1 *Concrete grammar* of [ITU-T Z.102].

NOTE 1 – For this mapping of <task body>, the <task body> is transformed into a <compound statement> as above, and then the <compound statement> is transformed and mapped as shown in clause F2.2.8.14.1. As a consequence, the transform of a <task> containing a <task body> is not necessarily mapped onto a Task-node.

```
< <task>( al ) >
provided al ∉ ( <task body> ∪ <informal text> ) // therefore legacy task body. al is <assignment>+
=3=>
< mk-<compound statement>( undefined, undefined, // no connector name, no variables
    mk-<statements>( < mk-<non terminating statement>( undefined, al[i] ) : i ∈ 1.. al.length > )
    ) // compound statement
>
```

NOTE 2 – Similar to the mapping of <task body> with variable definitions and a<statements>, the <task body> with a <legacy task body> is transformed into a <compound statement>, and then the <compound statement> is transformed and mapped as shown in clause F2.2.8.14.1.

NOTE 3 – The concrete syntax of <legacy task body> is distinguished from a <task body> only containing assignments by the punctuation used: a <legacy task body> has assignments separated by commas, whereas in a <task body> each assignment is terminated by a semi-colon. See clause 11.13.1 *Concrete grammar* of [ITU-T Z.103].

## Mapping to abstract syntax

```
| <task>(t) then mk-Graph-node(Mapping(t))
```

## Auxiliary functions

The function *assignmentTaskAction0* provides the representation of a single assignment in a task symbol (used - for example - in the model for remote procedures) as an <action>, where the variable <identifier> and <operand5> expression are given as parameters. This function is therefore used where an <action> to assign to a simple variable is needed. This function is not used in this clause.

```
assignmentTaskAction0(v: <identifier>, e: <operand5>): <action> =def
mk-<action>(
    undefined, // omitted <label> of <action>
    mk-<task>( mk-<task body>(
        empty, // empty variable definition list of <task body>
        < // <task body> <statements>=<non terminating statements>=<non terminating statement> list
            undefined, // omitted <connector name> of <non terminating statement>
            mk-<assignment statement>( v, e )
        > // end <task body> <statements>=<non terminating statements>=<non terminating statement> list
    )) // )<task body><task>
) // )<action>
```

### F2.2.8.13.2 Create

#### Abstract syntax

```
Create-request-node :: { Agent-identifier | THIS }
                    Actual-parameters
```

#### Conditions on abstract syntax

```
∀n ∈ Create-request-node:
    ( n.s-implicit ∉ Agent-identifier // THIS )
```

$\Rightarrow \text{parentAS1ofKind}(n, \text{agent type}) \neq \text{undefined}$  )

**THIS** shall only be specified in an *Agent-type-definition* and in scopes enclosed by an *Agent-type-definition*. See clause 11.13.2 *Abstract grammar* of [ITU-T Z.101].

```

 $\forall n \in \text{Create-request-node}$ :
  isActualAndFormalParameterMatched1
  (
    n.s-Expression-seq,
    if n.s-implicit  $\in$  Agent-identifier
    then // Agent-identifier
      getEntityDefinition1(
        getEntityDefinition1(n.s-Agent-identifier, agent).s-Agent-type-identifier,
        agent type).formalParameterSortList1
    else // THIS
      parentAS1ofKind(n, agent type).formalParameterSortList1
    endif
  ) // isActualAndFormalParameterMatched1

```

The length of the *Actual-parameters* list shall be the same as the number of *Agent-formal-parameters* in the *Agent-definition* of the *Agent-identifier*. Each *Expression* of *Actual-parameters* corresponding by position to an *Agent-formal-parameter* shall have a sort that is compatible to the sort of the *Agent-formal-parameter* in the *Agent-definition* denoted by *Agent-identifier*, or the local *Agent-type-definition* if **THIS** is given. See clause 11.13.2 *Abstract grammar* of [ITU-T Z.101].

### Concrete syntax

```

<create request> :: <create body>
<create body> :: { <identifier> | this } [ <actual parameters> ]

```

### Transformations

The following statement is formalized in the dynamic semantics.

**THIS** identifies the *Agent-identifier* of the set of instances of the agent in which the create is being interpreted.

```

c=<create request>( <create body>(id, params))
provided id.refersto0  $\in$  <agent type definition>  $\wedge$  c.possibleInstances0  $\neq$  empty
=8=>
(
  let inst = c.possibleInstances0 in
    if inst.length = 1
    then mk-<create request>( mk-<create body>(inst.head.identifier0, params))
    else // inst.length >1 - cannot be zero because possibleInstances0 not empty
      mk-<decision>(any, mk-<textual decision body>( <
        mk-<textual answer part>(undefined,
          mk-<transition action items>( mk-<action>(undefined,
            mk-<create request>( mk-<create body>(elem.identifier0, params)),
            undefined))
          | elem in inst >, undefined))
      endif
    endlet // inst
)

```

The ASM above formalizes the following paragraphs from items (a) and (b) clause 11.13.2 *Model* of [ITU-T Z.103].

If <agent type identifier> is used in a <create body> of a <create request> and there exists one instance set (explicit or implicit) of the indicated agent type in the agent containing the instance that performs the create, the <agent type identifier> is derived syntax denoting this instance set.

If <agent type identifier> is used in a <create body> of a <create request> and there is more than one (explicit) instance set, it is determined at interpretation time in which set the instance will be created. The <create request> is in this case replaced by a non-deterministic decision using any followed by

one branch for each instance set. In each of the branches a create request for the corresponding instance set is inserted.

```

let nn = newName in
  c = <create request>(<create body>(id, params))
provided id.refersto0 ∈ <agent type definition> ∧ c.possibleInstances0 = empty
=8=>
  mk-<create request>(mk-<create body>(mk-<identifier>(undefined, nn), params))
and
  astruct = <agent structure>(entities, defs, sm)
provided astruct = parentAS0ofKind(c, <agent structure>)
=>
  mk-<agent structure>(entities, // unchanged entities
    defs ∪ { // include the type based agent definition in the defs set
      if id.refersto0 ∈ <system type definition>
        then mk-<textual typebased system definition>(
          mk-<typebased system heading>(nn,
            mk-<type expression>(id, empty)))
        elseif id.refersto0 ∈ <block type definition>
          then mk-<textual typebased block definition>(
            mk-<typebased block heading>(nn, mk-<number of instances>(undefined, undefined),
              mk-<type expression>(id, empty)))
          else id.refersto0 ∈ <process type definition>
            then mk-<textual typebased process definition>(
              mk-<typebased process heading>(nn, mk-<number of instances>(undefined, undefined),
                mk-<type expression>(id, empty)))
            endif
          },
        sm
      )
    )
endlet // nn

```

If <agent type identifier> is used in a <create body> of a <create request> and there is no explicit instance set of the indicated agent type in the containing agent, the <agent type identifier> in the <create request> is derived syntax for this implicit instance set in this context, which has a unique name. See clause 11.13.2 *Model* of [ITU-T Z.103] item (c).

## Auxiliary functions

The following function aims at finding the possible instances for an agent type create request.

$$possibleInstances0(c: \langle \text{create request} \rangle): \langle \text{agent definition} \rangle^* \stackrel{\text{def}}{=} \\ \langle e \text{ in } parentAS0ofKind(c, \langle \text{agent definition} \rangle \cup \langle \text{agent type definition} \rangle).getEntities0: \\ e \in \langle \text{agent definition} \rangle \wedge e.s-\langle \text{type expression} \rangle.s-\langle \text{base type} \rangle = c.s-\langle \text{create body} \rangle.s-\text{implicit} \rangle$$

## Mapping to abstract syntax

| <create request>(c **then** **mk**-*Graph-node*(*Mapping*(c))

| <create body>(id, *params*) **then** **mk**-*Create-request-node*(*Mapping*(id), *Mapping*(*params*))

### F2.2.8.13.3 Procedure call

#### Abstract syntax

*Call-node* :: [ **THIS** ] *Procedure-identifier* *Actual-parameters*

#### Conditions on abstract syntax

$$\forall n \in \text{Call-node} \cup \text{Value-returning-call-node}: \forall d \in \text{Procedure-definition}: \\ ( (d = getEntityDefinition1(n.s-\text{Procedure-identifier}, \text{procedure})) \Rightarrow \\ ( d.s-\text{Procedure-graph}.s-\text{Procedure-start-node} \neq \text{undefined} \\ \wedge$$

```

isActualAndFormalParameterMatched(n.s-Actual-parameters.s-implicit-seq,
  d.formalParameterSortListI) // in or inout or out parameters sort match
^
(∀i ∈ 1..n.s-Actual-parameters.s-implicit-seq.length:
  ( d.formalParameterListI[i] ∈ Inout-parameter ∪ Out-parameter ⇒
    n.s-Expression[i] ∈ Identifier
    ^
    n.s-Expression[i].idKindI = variable
  )
) ) ) )

```

The *Procedure-identifier* shall identify a *Procedure-definition* with a *Procedure-graph* that has a *Procedure-start-node*. The length of the *Actual-parameters* list shall be the same as the number of the *Procedure-formal-parameter* items in the *Procedure-definition* denoted by the *Procedure-identifier*. Each *Expression* in the *Actual-parameters* list corresponding by position to an *In-parameter* shall be sort compatible to the sort of the *Procedure-formal-parameter*. Each element in the *Actual-parameters* list corresponding by position to an *Inout-parameter* or *Out-parameter* shall be an *Expression* for a *Variable-identifier* with the same *Sort-reference-identifier* as the *Procedure-formal-parameter*. See clause 11.13.3 *Abstract grammar* of [ITU-T Z.101].

### Concrete syntax

```

<procedure call> :: <procedure call body>
<procedure call body> ::
  [ this ] <procedure><type expression> [ <actual parameters> ]

```

### Transformations

```

p = <procedure call body>( t, te, params) // t = this or undefined, id = type expression
provided parentASOfKind(te.baseType0, <agent type definition>) ≠
  parentASOfKind(p, <agent type definition>)
=8=>
let par = parentASOfKind(p, <agent type definition>) in
mk-<procedure call body>( t,
  mk-<type expression>(
    mk-<identifier>( par.fullQualifierWithin0, te.baseType0.entityName0), //local procedure, same name
  ) // type expression
  params)
endlet // par
and // add the new definition if it does not exist
let par = parentASOfKind(p, <agent type definition>) in
let defs = par.s-<agent structure>.s-<entity in agent>-seq in
let procDef =
mk-<internal procedure definition>( empty, // <package use clause>*
  mk-<procedure heading>(
    mk-<procedure preamble>(
      mk-<type preamble>( finalized, undefined), //finalized, not abstract
      undefined), // not exported – end procedure preamble
      empty, // defined in context – no qualifier
      te.baseType0.entityName0, // same name as original
      empty, // no formal context parameters
      undefined, // virtuality constraint
      mk-<specialization>( te), // specialization is type expression given in call
      empty, // no additional formal parameters
      te.baseType0.s-<procedure heading>.s-<result> // same result
    ), // procedure heading
    mk-<procedure body>( undefined, empty) // no additional start, empty {state/free action} list
  ) // internal procedure definition
in
defs => defs ^ if procDef in defs then empty else <procDef> endif
endlet // procDef
endlet // defs

```

**endlet** // *par*

If the procedure identified by the <procedure type expression> of the <procedure call body> is not defined within the agent type enclosing the call, within the enclosing agent type there is an implicitly defined local procedure with the same name as identified by the <procedure type expression> and the call uses this local procedure. In the local procedure, identifiers of items (such as variables) external to the procedure definition are bound in the context of the original procedure definition rather than the context of the procedure call if that is different. An implicitly defined local procedure is an inherited subtype of the procedure identified by the <procedure type expression> of the <procedure call body>. See clause 11.13.3 *Model* of [ITU-T Z.101].

### Mapping to abstract syntax

```
| <procedure call>(p) then mk-Graph-node(Mapping(p))

| p=<procedure call body>(t, te, params) then
  mk-Call-node(Mapping(t),
    if Mapping(t) ≠ THIS // THIS absent
    ∧ parentASOfKind(te.baseType0, <agent type definition>) =
      parentASOfKind(p, <agent type definition>) // base type in local agent type
    then Mapping(te.baseType0.s-<specialization>)
    else Mapping(te)
    endif // call base type or specialization
    Mapping(params)
  ) // Call-node
```

If **THIS** is present and the procedure is specialized, the *Procedure-identifier* refers to the identifier of the specialized procedure. For a procedure that is not specialized or if **THIS** is absent, the *Procedure-identifier* refers to the identifier of the procedure that is not specialized. See clause 11.13.3 *Semantics* of [ITU-T Z.102].

NOTE – The actual context parameters of the type expression of a procedure call are transformed before the mapping is done, so the type expression contains only a procedure identifier, which will be a procedure in the local agent type that is a local subtype transform of the originally referenced procedure if this was not in the local agent type. Such a local subtype transform is not specialized, therefore the local subtype procedure is called whether **THIS** is present or not. If the referenced procedure has a base type defined in the local agent, it is a specialized procedure, therefore if **THIS** is absent the base type procedure is called.

### F2.2.8.13.4 Output

#### Abstract syntax

<i>Output-node</i>	::	{ [ <b>BROADCAST</b> ] <i>Signal-identifier</i> <i>Actual-parameters</i>   <i>Expression</i>   <i>Encoded-expression</i> } <i>Activation-delay</i> <i>Signal-priority</i> [ <i>Signal-destination</i> ] <i>Direct-via</i>
<i>Activation-delay</i>	=	<i>Expression</i>
<i>Signal-priority</i>	=	<i>Expression</i>
<i>Signal-destination</i>	::	{ <i>Expression</i>   <i>Agent-identifier</i>   <b>THIS</b> } [ <i>Destination-number</i> ]
<i>Destination-number</i>	=	<i>Expression</i>
<i>Direct-via</i>	=	<i>Gate-identifier-set</i>
<i>Encoded-expression</i>	::	<i>Expression</i>

#### Conditions on abstract syntax

∀ *onode* ∈ *Output-node*:

$onode.s\text{-implicit.s-Identifier} \neq \text{undefined} \Rightarrow // \text{Signal-identifier - not Expression or Encoded-expression}$   
 $(\exists sd \in \text{Signal-definition:}$   
 $(sd = \text{getEntityDefinition1}(onode.s\text{-implicit.s-Identifier}, \text{signal})) \wedge$   
 $isActualAndFormalParameterMatched1(onode.s\text{-implicit.s-Expression-seq},$   
 $sd.\text{formalParameterSortList1}))$

The length of the *Actual-parameters* list shall be the same as the number of *Signal-parameter* items in the *Signal-definition* denoted by the *Signal-identifier*. See clause 11.13.4 *Abstract grammar* of [ITU-T Z.101].

Each *Expression* of the *Actual-parameters* shall be sort compatible with the *Sort-reference-identifier* of the corresponding (by position) *Signal-parameter* of the *Signal-definition*. See clause 11.13.4 *Abstract grammar* of [ITU-T Z.101].

NOTE 1 – The ASM code above requires both the conditions above are met.

$\forall onode \in \text{Output-node: } onode.s1\text{-Expression.staticSort1} = \text{predefinedId1}(\text{"Duration"})$

The *Expression* of the *Activation-delay* shall be a *Duration* expression. See clause 11.13.4 *Abstract grammar* of [ITU-T Z.101].

$\forall onode \in \text{Output-node: } onode.s2\text{-Expression.staticSort1} = \text{predefinedId1}(\text{"Natural"})$

The *Expression* of the *Signal-priority* shall be a *Natural* expression. See clause 11.13.4 *Abstract grammar* of [ITU-T Z.101].

$\forall onode \in \text{Output-node:}$   
**let**  $sigid = onode.s\text{-implicit.s-Identifier}$  // *Signal-identifier*  
**in**  
**let**  $dv = onode.s\text{-Identifier-set}$  // *Direct-via*  
**in**  
 $sigid \neq \text{undefined} \wedge dv \neq \emptyset \Rightarrow$   
 $(\forall gi \in dv:$   
 $gi \in \text{reachableGatesWithSignal1}(\text{enclosingScopeGates1}(\text{parentAS1ofKind}(onode, \text{Composite-state-type-definition})), sigid)$   
 $\wedge sigid \in \text{getEntityDefinition1}(gi, \text{gate}).s\text{-Out-signal-identifier-set})$   
**endlet** //  $dv$   
**endlet** //  $sigid$

For each *Gate-identifier* in *Direct-via*, there shall exist zero or more channels such that the gate via this path is reachable with the *Signal-identifier* from the agent and the *Out-signal-identifier-set* of the gate shall include the *Signal-identifier*. See clause 11.13.4 *Abstract grammar* of [ITU-T Z.101].

$\forall onode(*, *, *, sd(d, *), *) \in \text{Output-node: } // sd \in \text{Signal-destination}$   
**let**  $sigid = onode.s\text{-Identifier}$  // *Signal-identifier*  
**in**  
 $sigid \neq \text{undefined} \wedge sd \neq \text{undefined} \Rightarrow$   
**case**  $d$  **of**  
| *Expression* **then**  
**if**  $staticSort1(d) = \text{predefinedId1}(\text{"Pid"})$  **then** *true*  
**else**  
**let**  $ifd = \text{getEntityDefinition1}(staticSort1(d), \text{sort})$   
**in**  
**if**  $ifd = \text{undefined} \vee ifd \notin \text{Interface-definition}$  **then** *false*  
**else**  $sigid \in ifd.s\text{-Identifier-set}$   
**endif**  
**endlet**  
**endif**  
| *Identifier* **then**  
 $d \in \text{reachableAgentsWithSignal1}(\text{enclosingScopeGates1}(\text{parentAS1ofKind}(onode, \text{Composite-state-type-definition})), sigid)$   
**otherwise** *true*  
**endcase**  
**endlet** //  $sigid$

The sort of *Expression* of a *Signal-destination* shall either be the sort *Pid* (see clause 12.1.5), or the sort *Interface-definition* with the *Signal-identifier* in its *Signal-identifier-set*. See clause 11.13.4 *Abstract grammar* of [ITU-T Z.101].

The *Agent-identifier* of a *Signal-destination* shall identify an agent reachable from the originating agent. See clause 11.13.4 *Abstract grammar* of [ITU-T Z.101].

NOTE 2 – The ASM code above requires both the conditions above are met.

$\forall sigdest \in \text{Signal-destination}: sigdest.\mathbf{s-implicit} \in \text{Expression} \Rightarrow sigdest.\mathbf{s-Destination-number} = \text{undefined}$

The *Destination-number* is always omitted for a *Signal-destination* that is an *Expression*. See clause 11.13.4 *Abstract grammar* of [ITU-T Z.101].

```

 $\forall onode(*, *, *, *, dv) \in \text{Output-node} :$ 
 $((onode.\mathbf{s-BROADCAST} \neq \text{undefined}) \Rightarrow // \text{is broadcast, therefore the following shall be true}$ 
let  $sigid = onode.\mathbf{s-Identifier} // \text{Signal-identifier}$ 
in
  // if more than one gate identifier given in Direct-via, they have to be on the same communication path
  // or there shall be no agent reachable by both paths
   $\forall gid1 \in dv : ( // \text{see above for constraints on Gate-identifier in Direct-via}$ 
     $\forall gid2 \in dv \setminus \{gid1\} :$ 
       $gid2 \in \text{reachableGatesWithSignal1}(\{gid1\}, sigid) // gid2 \text{ can be reached from } gid1, \text{ or}$ 
       $\vee gid1 \in \text{reachableGatesWithSignal1}(\{gid2\}, sigid) // gid1 \text{ can be reached from } gid2, \text{ or}$ 
       $\vee (\text{reachableAgentsWithSignal1}(\{gid1\}, sigid) \cap \text{reachableAgentsWithSignal1}(\{gid2\}, sigid)$ 
         $= \emptyset // \text{no agent reachable from both } gid1 \text{ and } gid2$ 
      )
    ) // for all  $gid2$ 
  ) // for all  $gid1$ 
endlet  $sigid$ 
) // for all  $onode$ 

```

If an *Output-node* includes **BROADCAST**, for the given *Signal-identifier*, *Signal-destination*, and *Direct-via* there shall be no more than one communication path to a reachable agent instance set. If a gate is on the same communication path as another gate, either the first gate can be reached from the second gate, or the second gate can be reached from the first gate. If an agent is reachable from a gate of one path, that agent shall not be reachable from a gate of another path. See clause 11.13.4 *Abstract grammar* of [ITU-T Z.102].

```

 $\forall onode \in \text{Output-node}: onode.\mathbf{s-implicit} \in \text{Expression} \Rightarrow$ 
 $\exists gt \in \langle \text{textual gate definition} \rangle : ( // \text{make sure local gate}$ 
   $\text{Mapping}(gt) \in \text{enclosingScopeGates1}(\text{parentAS1ofKind}(onode, \text{Composite-state-type-definition}))$ 
   $\wedge onode.\mathbf{s-implicit}.staticSort1 = gt.\text{choiceForGate1} // \text{corresponding choice for gate}$ 
)

```

If an *Output-node* has an *Expression* (instead of *Signal-identifier* followed by *Actual-parameters*) the sort of the *Expression* shall be the sort of a choice data type, where choice fields correspond to outgoing signals carried from the local agent by one of the gates of the agent. A choice field of the choice data type corresponds if its field name is the same as:

- a) a signal name that unambiguously identifies an outgoing signal; or
- b) the unique anonymous *Sort* name for a *Data-type-definition* for a structure data type, denoted by an  $\langle \text{as signal} \rangle$  that identifies an outgoing signal;

and the sort of the choice field is a structure data type where the sort of each field of the structure is the same as the corresponding (by position) parameter of the identified outgoing signal. See clause 11.13.4 *Abstract grammar* of [ITU-T Z.104].

```

 $\forall onode \in \text{Output-node}: onode.\mathbf{s-implicit} \in \text{Encoded-expression} \Rightarrow$ 
 $onode.\mathbf{s-implicit}.staticSort1 \in$ 
 $(\text{predefinedId1}(\text{"Charstring"}) \cup \text{predefinedId1}(\text{"Octetstring"}) \cup \text{predefinedId1}(\text{"Bitstring"}))$ 

```

If an *Output-node* has an *Encoded-expression* (instead of *Signal-identifier* followed by *Actual-parameters*) the sort of the *Expression* of the *Encoded-expression* shall be Charstring, Octetstring or Bitstring. The *Direct-via* shall have exactly one *Gate-identifier*, and this shall identify a gate that has *Encoding-rules* with the same sort (Charstring, Octetstring or Bitstring) as the *Expression* of the *Encoded-expression*. See clause 11.13.4 *Abstract grammar* of [ITU-T Z.104].

## Concrete syntax

```

<output> :: <output body>
<output body> :: <output body item>+ <communication constraints>
<output body item> ::
  { <signal<identifier> [<actual parameters>] | <expression output> | <encoded output> }
  [<activation delay>][<signal priority>]
<expression output> :: <expression>
<encoded output> :: <expression>
<communication constraints> = { <timer communication constraint> | <destination> | <via path> }*
<destination> ::
  <pid<expression>
  | { [ system | block | process ] <agent<identifier> | this } [<destination number>]
  | all { [ system | block | process ] <agent<identifier> | this }
<activation delay> :: <Duration<expression>
<signal priority> :: <Natural<expression>
<destination number> :: <Natural<expression>

```

## Conditions on concrete syntax

```

∀d∈<destination>:
  ((d.s-system ≠ undefined
    ⇒ (getEntityDefinition0(d.s-<identifier>, agent).entityKind0 = system))
  ∧ ((d.s-block ≠ undefined
    ⇒ (getEntityDefinition0(d.s-<identifier>, agent).entityKind0 = block))
  ∧ ((d.s-process ≠ undefined
    ⇒ (getEntityDefinition0(d.s-<identifier>, agent).entityKind0 = process))

```

The optional keyword (**system**, **block** or **process**) before an <agent identifier> in <destination> shall match the *Agent-kind*. See clause 11.13.4 *Concrete grammar* of [ITUT Z.101].

## Transformations

```

<output>( <output body> (olist, clist))
provided <clist[i] | i in 1..clist.length : clist[i] ∈ <destination> >.length > 1
=8=>
mk-<output>( mk-<output body> ( olist, // list with just first dest
  <clist[i] | i in 1..clist.length :
    (clist[i] ∉ <destination>) ∨ ¬(∃ j ∈ 1..clist.length : j < i ∧ clist[j] ∈ <destination>)
  )
)
mk-<output>( mk-<output body> ( olist, // list without first dest
  <clist[i] | i in 1..clist.length :
    (clist[i] ∉ <destination>) ∨ (∃ j ∈ 1..clist.length : j < i ∧ clist[j] ∈ <destination>)
  )
)

```

If <communication constraints> of an <output body> of an <output area> contains more than one **to** <destination> clause, this is a shorthand for replacing the <output area> by an <output area> sequence, one for each **to** <destination>. Each <output area> has the same original <output body

item> list, but in each case the <communication constraints> contains only one **to** <destination> taken in order from the original <communication constraints>. See clause 11.13.4 *Model* of [ITU-T Z.103].

```

<output>( <output body>(outputList, constr))
provided outputList.length > 1
=8=>
mk-<output>(mk-<output body>( < outputList.head >, constr)) ^
if outputList.length > 1
then mk-<output>(mk-<output body>( outputList.tail, constr))
else empty
endif

```

If there is more than one <output body item> specified in an <output body> of an <output>, the <output> is transformed into an <output> sequence each with a single <output body item> in the same order as specified in the original <output >. The <communication constraints> are repeated in each <output body>. See clause 11.13.4 *Model* of [ITU-T Z.103].

*The following statement is covered by the dynamic semantics.*

Stating **this** in <destination> is derived syntax for the implicit <agent identifier> that identifies the set of instances for the agent in which the output is being interpreted.

### Mapping to abstract syntax

```

| <output>(o) then mk-Graph-node(Mapping(o))

| <output body>( < <output body item>( sig, pars, delay, priority) >, constr) then // Sig Id, Actual parameters
mk-Output-node(
  if constr.s-<destination>. s-all ≠ undefined then BROADCAST else undefined endif, // broadcast
  Mapping(sig), // Signal Identifier
  if pars = undefined // no actual parameters in output body item
  then mk-Actual-parameters(empty) // empty sequence for Actual-parameters
  else mk-Actual-parameters( < // list of actual parameters – each one an expression or undefined
    if pars[i] ≠ undefined then Mapping(pars[i]) else UNDEFINED endif : i ∈ 1.. pars.length
  >)
  endif,
  Mapping(delay),
  Mapping(priority),
  Mapping(head(< c in constr: (c ∈ <destination>) >)), // Signal destination
  { Mapping(c in constr): c ∈ <via path> } // set of via path gate id mappings – Direct via
) // Output-node

| <output body>( < <output body item>(sigexpr, delay, priority) >, constr) then
// is expression output, or encoded output
mk-Output-node(
  undefined, // broadcast
  Mapping(sigexpr)
  Mapping(delay),
  Mapping(priority),
  Mapping(head(< c in constr: (c ∈ <destination>) >)), // Signal destination
  { Mapping(c in constr): c ∈ <via path> } // set of via path gate id mappings – Direct via
) // Output-node

| <expression output>(expr) then Mapping(expr)

| <encoded output>(expr) then mk-Encoded-expression(Mapping(expr))

| <activation delay>(delayexpr) then
  if delayexpr = undefined
  then predefinedLiteralI("Duration", "0")
  else Mapping(delayexpr)
  endif

```

```

| <signal priority>(priorityexpr) then
  if priorityexpr = undefined
  then predefinedLiteral1("Natural", "0")
  else Mapping (priorityexpr)
  endif

| <destination>(d) then
  if (d.s-implicit.s-<identifier> = undefined ∧ d.s-implicit.s-this = undefined) // neither id or this
    ∨ ( d.s-implicit.s-<identifier> ≠ undefined ∧ ¬(d.s-implicit.s-<identifier>.refersto0 ∈
      (<system definition> ∪ <block definition> ∪ <agent definition>))) // or is id but not agent
  then mk-Signal-destination(Mapping(d), undefined) // pid expression
  elseif d.s-implicit.s-<identifier> ≠ undefined // is agent id with optional destination number
  then mk-Signal-destination(Mapping(d.s-implicit.s-<identifier>,
    Mapping(d.s-implicit.s-<destination number>))
  else mk-Signal-destination(THIS, Mapping(d.s-implicit.s-<destination number>))
  endif
// mapping of <via path> is in F2.2.8.3 Input, Mapping to abstract syntax

```

## Auxiliary functions

The function *usedSignalSet0* provides the set of signal identifiers defined by the list of signal list items in the interface use lists of the given interface definition and any interface use lists of inherited interface definitions. It does not include signals defined by the interface definition or defined by inherited interface definitions.

```

usedSignalSet0(id: <interface definition>): SIGNAL0 =def
{ sig ∈ ( interfaceUseList.s-<signal list item>-seq.signalSet0):
  ( interfaceUseList ∈ <interface use list>
    ∧ parentAS0ofKind (interfaceUseList, <interface definition>) = id
  ) }
∪
{ sig ∈ (interfaceUseList1.s-<signal list item>-seq.signalSet0):
  ( interfaceUseList1 ∈ <interface use list>
    ∧ (∃ id1 ∈ <interface definition>: (isSubtype0(id, id1))
      ∧ parentAS0ofKind (interfaceUseList1, <interface definition>) = id1)
  ) }

```

The function *definedSignalSet0* provides the set of signal definitions in the signal definition list items of the given interface definition and any signal definitions of inherited interface definitions.

```

definedSignalSet0(id: <interface definition>): <signal definition>-set =def
{ sd ∈ <signal definition>:
  ( (sd.parentAS0 ∈ <signal definition list>) ∧ (sd.parentAS0.parentAS0 = id))
  ∨
  ( (∃ id1 ∈ <interface definition>: isSubtype0(id, id1)) ∧
    (sd.parentAS0 ∈ <signal definition list>) ∧ (sd.parentAS0.parentAS0 = id1)) }

```

The function *enclosingScopeGates1* is used to find the nearest *Composite-state-type-definition* or *Agent-type-definition* item with gates that encloses an *Output-node*, and returns a gate *Identifier-set* for the gates.

```

enclosingScopeGates1(td: Composite-state-type-definition ∪ Agent-type-definition):
  Identifier-set =def
if td = undefined then ∅
else
  if td.s-Gate-definition-set = ∅
  then
    enclosingScopeGates1(parentAS1ofKind(td, Composite-state-type-definition ∪ Agent-type-definition))
  else
    { gd.identifier1 | gd ∈ td.s-Gate-definition-set }
  endif

```

**endif**

The function *reachableGatesWithSignal1* returns the gate *Identifier-set* for gates that are reachable from the given gate *Identifier-set* with the given signal *Identifier*. A gate is reachable from one of the gates given if there is a channel path with the one of the given gates as an originating gate and the gate as a destination gate. The given signal has to be conveyed by the channel. The originating gate has to be a gate defined for the origin channel endpoint and the signal has to be a valid signal in the correct direction for this gate. The destination gate has to be a gate defined for the destination channel endpoint and the signal has to be a valid signal in the correct direction for this gate.

```
reachableGatesWithSignal1(gset: Identifier-set, sigid: Identifier): Identifier-set =def
let gis = { gi |
    cp ∈ Channel-path
    ∧ cp.s-Originating-gate ∈ gset
    ∧ gi ∈ cp.s-Destination-gate
    ∧ sigid ∈ cp.s-Identifier-set
    ∧ getEntityDefinition1(cp.s-Originating-gate, gate) ∈
        case cp.s1-Channel-endpoint of
        | id = Identifier then
            if getEntityDefinition1(id, agent) ≠ undefined
            then
                getEntityDefinition1(getEntityDefinition1(id, agent).s-Identifier,
                    agent type).s-Gate-definition-set
            else
                getEntityDefinition1(parentAS1ofKind(cp, Agent-type-definition).s-State-machine.s-Identifier,
                    state type).s-Gate-definition-set
            endif
        | ENV then
            parentAS1ofKind(cp, Agent-type-definition).s-Gate-definition-set
        endcase
    ∧ sigid ∈
        case cp.s1-Channel-endpoint of
        | Identifier then getEntityDefinition1(cp.s-Originating-gate, gate).s2-Identifier-set
        | ENV then getEntityDefinition1(cp.s-Originating-gate, gate).s1-Identifier-set
        endcase
    ∧ getEntityDefinition1(cp.s-Destination-gate, gate) ∈
        case cp.s2-Channel-endpoint of
        | id = Identifier then
            if getEntityDefinition1(id, agent) ≠ undefined
            then
                getEntityDefinition1(getEntityDefinition1(id, agent).s-Identifier,
                    agent type).s-Gate-definition-set
            else
                getEntityDefinition1(parentAS1ofKind(cp, Agent-type-definition).s-State-machine.s-Identifier,
                    state type).s-Gate-definition-set
            endif
        | ENV then
            parentAS1ofKind(cp, Agent-type-definition).s-Gate-definition-set
        endcase
    ∧ sigid ∈
        case cp.s2-Channel-endpoint of
        | Identifier then getEntityDefinition1(cp.s-Destination-gate, gate).s1-Identifier-set
        | ENV then getEntityDefinition1(cp.s-Destination-gate, gate).s2-Identifier-set
        endcase }
in
    gset ∪ if gis = ∅ then ∅ else reachableGatesWithSignal1(gis, sigid) endif
endlet
```

The function *reachableAgentsWithSignal1* returns the agent *Identifier-set* for agents that are reachable from the given gates with the given signal *Identifier*. The function is called with a gate *Identifier-set* for the gates on an agent. The paths from these gates that carry the given signal are

found. The *Identifier-set* with the name agents is the set of agents directly reachable via these paths. If there are paths that lead to gates for environment of the agent, there can be additional agents reachable from these gates.

```

reachableAgentsWithSignal1(sourceGates: Identifier-set, sigid: Identifier): Identifier-set =def
let paths = {cp ∈ Channel-path:
    cp.s1-Channel-endpoint ∈ sourceGates
    ∧ sigid ∈ cp.s-Identifier-set
    ∧ sigid ∈
        case cp.s1-Channel-endpoint of
        | Identifier then getEntityDefinition1(cp.s-Originating-gate, gate).s2-Identifier-set
        | ENV then getEntityDefinition1(cp.s-Originating-gate, gate).s1-Identifier-set
        endcase
    ∧ sigid ∈
        case cp.s2-Channel-endpoint of
        | Identifier then getEntityDefinition1(cp.s-Destination-gate, gate).s1-Identifier-set
        | ENV then getEntityDefinition1(cp.s-Destination-gate, gate).s2-Identifier-set
        endcase }
in
let agents = {a ∈ Identifier:

let gates = {g ∈ Identifier:
    cp ∈ paths
    ∧ g ∈ cp.s2-Identifier}
in
agents ∪ if gates = ∅ then ∅ else reachableAgentsWithSignal1(gates, sigid) endif
endlet
endlet
endlet

```

### F2.2.8.13.5 Decision

#### Abstract syntax

<i>Decision-node</i>	::	<i>Decision-body</i>   <i>Any-decision</i>
<i>Decision-body</i>	::	<i>Decision-question</i> <i>Decision-answer-set</i> [ <i>Else-answer</i> ]
<i>Decision-question</i>	=	<i>Expression</i>   <i>Informal-text</i>
<i>Decision-answer</i>	::	{ <i>Range-condition</i>   <i>Informal-text</i> } <i>Transition</i>
<i>Else-answer</i>	::	<i>Transition</i>
<i>Any-decision</i>	::	<i>Transition-set</i>

#### Conditions on abstract syntax

$$\begin{aligned}
 &\forall dn \in \text{Decision-question}: \forall r, r1 \in \text{Range-condition}: \forall ce, ce1 \in \text{Constant-expression}: \\
 &isAncestorASI(r, ce) \wedge isAncestorASI(r1, ce1) \wedge (ce \neq ce1) \wedge \\
 &r1.parentASI \in dn.s\text{-Decision-answer-set} \wedge r.parentASI \in dn.s\text{-Decision-answer-set} \Rightarrow \\
 & \quad ( isCompatibleTo1( ce.staticSort1, ce1.staticSort1) \vee \\
 & \quad isCompatibleTo1( ce1.staticSort1, ce.staticSort1) ) \wedge \\
 &(dn.s\text{-Decision-question} \in \text{Expression} \Rightarrow \\
 & \quad isCompatibleTo1( ce.staticSort1, dn.s\text{-Decision-question}.staticSort1))
 \end{aligned}$$

Each *Constant-expression* of the *Range-condition* shall be sort compatible with the sort of the *Decision-question*. If the *Decision-question* is an *Expression*, the *Range-condition* of each *Decision-*

*answer* shall be sort compatible with the sort of the *Decision-question*. See clause 11.13.5 *Abstract grammar* of [ITU-T Z.106].

## Concrete syntax

$\langle \text{decision} \rangle :: \langle \text{question} \rangle \langle \text{textual decision body} \rangle$   
 $\langle \text{textual decision body} \rangle :: \langle \text{textual answer part} \rangle + [ \langle \text{textual else part} \rangle ]$   
 $\langle \text{textual answer part} \rangle :: [ \langle \text{answer} \rangle ] [ \langle \text{transition} \rangle ]$   
 $\langle \text{answer} \rangle = \langle \text{range condition} \rangle \mid \langle \text{informal text} \rangle$   
 $\langle \text{textual else part} \rangle :: [ \langle \text{transition} \rangle ]$   
 $\langle \text{question} \rangle = \langle \text{expression} \rangle \mid \langle \text{informal text} \rangle \mid \mathbf{any}$

## Conditions on concrete syntax

$\forall d \in \langle \text{decision} \rangle: (d.s\text{-}\langle \text{question} \rangle = \mathbf{any}) \Leftrightarrow$   
 $\neg(\exists ap \in \langle \text{textual answer part} \rangle: (ap.\text{parentAS0}.\text{parentAS0} = d)) \wedge (ap.s\text{-}\langle \text{answer} \rangle \neq \text{undefined}) \wedge$   
 $(d.s\text{-}\langle \text{textual decision body} \rangle.s\text{-}\langle \text{textual else part} \rangle = \text{undefined})$

The  $\langle \text{answer} \rangle$  of  $\langle \text{textual answer part} \rangle$  shall be omitted if and only if the  $\langle \text{question} \rangle$  consists of the keyword **any**. In this case, a  $\langle \text{textual else part} \rangle$  shall be absent. See clause 5.7.12.5 of [ITU-T Z.106].

## Transformations

See clause 5.7.12.5 of [ITU-T Z.106].

$\langle \text{textual else part} \rangle(\text{undefined}) =5=>$   
 $\mathbf{mk}\text{-}\langle \text{textual else part} \rangle(\mathbf{mk}\text{-}\langle \text{transition action items} \rangle(\text{empty}, \text{undefined}))$

$\langle \text{textual answer part} \rangle(a, \text{undefined}) =5=>$   
 $\mathbf{mk}\text{-}\langle \text{textual answer part} \rangle(a, \mathbf{mk}\text{-}\langle \text{transition action items} \rangle(\text{empty}, \text{undefined}))$

These first two transformations are used to insert an empty transition instead of an undefined one. This empty transition will be filled with a terminator within the step below (inserting terminating actions into the transition).

$t = \langle \text{transition action items} \rangle(a, \text{undefined})$   
**provided**  $a.\text{last} \notin \langle \text{decision} \rangle \wedge t.\text{parentAS0}.\text{parentAS0}.\text{parentAS0} \in \langle \text{decision} \rangle \wedge$   
 $t.\text{findContinueLabel} \neq \text{undefined}$   
 $=5=> \mathbf{mk}\text{-}\langle \text{transition action items} \rangle(a,$   
 $\mathbf{mk}\text{-}\langle \text{terminator} \rangle(\text{undefined}, \mathbf{mk}\text{-}\langle \text{join} \rangle(\text{findContinueLabel}(t))))$

If a  $\langle \text{decision} \rangle$  is not terminating, it is derived syntax for a  $\langle \text{decision} \rangle$  where all not terminating  $\langle \text{textual answer part} \rangle$ s and the  $\langle \text{textual else part} \rangle$  (if not terminating) have inserted at the end of their  $\langle \text{transition} \rangle$  a  $\langle \text{join} \rangle$  to the first  $\langle \text{action} \rangle$  following the decision or (if the decision is the last  $\langle \text{action} \rangle$  in a  $\langle \text{transition string} \rangle$ ) to the following  $\langle \text{terminator} \rangle$ .

$\langle d = \langle \text{decision} \rangle(*, *) , \langle \text{action} \rangle(\text{undefined}, a) \rangle \mathbf{provided} \neg \text{terminatingDecision}(d)$   
 $=5=> \langle d , \langle \text{action} \rangle(\text{newName}, a) \rangle$

$\langle \text{transition action items} \rangle(\text{str}, \langle \text{terminator} \rangle(\text{undefined}, t))$   
**provided**  $\text{str}.\text{last} \in \langle \text{decision} \rangle \wedge \neg \text{str}.\text{last}.\text{terminatingDecision}$   
 $=5=> \mathbf{mk}\text{-}\langle \text{transition action items} \rangle(\text{str}, \mathbf{mk}\text{-}\langle \text{terminator} \rangle(\text{newName}, t))$

The rules above insert a new label after a non-terminating decision.

## Mapping to abstract syntax

$\mid \langle \text{decision} \rangle(q, \langle \text{textual decision body} \rangle(\text{answers}, \text{elseAnswer})) \mathbf{then}$   
 $\mathbf{if} \ q \neq \mathbf{any}$   
 $\mathbf{then} \ \mathbf{mk}\text{-}\text{Decision-node}(\text{Mapping}(q), \text{Mapping}(\text{answers}).\text{toSet}, \text{Mapping}(\text{elseAnswer}))$   
 $\mathbf{else} \ \mathbf{mk}\text{-}\text{Any-decision}(\text{Mapping}(\text{answers}))$

**endif**

```
| <textual answer part>(ans, trans) then  
  if ans≠undefined  
  then mk-Decision-answer(Mapping(ans), Mapping(trans))  
  else mk-Transition(Mapping(trans))  
  endif
```

If *ans*≠undefined the <textual answer part> is the *Decision-answer* of a *Decision-body*, otherwise the <textual answer part> is the *Transition* of an *Any-decision*.

```
| <textual else part>(trans) then  
  if trans=undefined  
  then undefined  
  else mk-Else-answer(Mapping(trans))  
  endif
```

## Auxiliary functions

```
rangeConditionList0(d:<decision>):<range condition>* =def  
  let apl = d.s-<textual decision body>.s-<textual answer part> in  
    apl.answerPartRangeConditionList0  
  endlet
```

```
answerPartRangeConditionList0(apl:<textual answer part>*):<range condition>* =def  
  if apl.head.s-<answer>∈<range condition> then  
    apl.head.s-<answer> ^ apl.tail.answerPartRangeConditionList0  
  else apl.tail.answerPartRangeConditionList0
```

The function *findContinueLabel* computes the continuation label after a decision within a transition string.

```
findContinueLabel(x: DefinitionAS0): <name> =def  
  if x ∈ <transition action items> ∧ x.s-<terminator> ≠ undefined ∧  
    x.s-<terminator>.s-<label> = undefined ∧  
    x.s-<terminator>.s-<terminator node> ∈ <join>  
  then x.s-<terminator>.s-<terminator node>.s-<name>  
  else findContinueLabel(x.parentAS0)  
  endif
```

```
terminatingDecision(d: <decision>): BOOLEAN =def  
  (∀ a ∈ d.s-<textual answer part>: terminatingTransition(a.s-<transition>)) ∧  
  (d.s-<textual else part> = undefined ∨  
    terminatingTransition(d.s-<textual else part>.s-<transition>))
```

A <decision> is a terminating decision, if each <textual answer part> and <textual else part> in its <textual decision body> is a terminating <textual answer part> or <textual else part> respectively.

```
terminatingTransition(t: <transition>): BOOLEAN =def  
  t ∈ <terminator> ∨  
  t.s-<terminator node> ≠ undefined ∨  
  (let d= t.s-<action>.last in d ∈ <decision> ∧ terminatingDecision(d) endlet)
```

A <textual answer part> or <textual else part> in a decision is a terminating <textual answer part> or <textual else part> respectively if it contains a <transition> where a <terminator> is specified, or contains a <transition string> whose last <action> contains a terminating decision.

### F2.2.8.14 Statement lists

#### Concrete syntax

```
<statements> ::  
  <non terminating statements> [ [ <connector name> ] <terminating statement> ]
```

```

    | [ <connector name> ] <terminating statement>
<non terminating statements> = <non terminating statement>+
<non terminating statement> ::
    [ <connector name> ] <statement>
    | <compound statement>
    | <loop statement>
    | <decision statement>
<statement> =
    <assignment statement>
    | <set statement>
    | <reset statement>
    | <output statement>
    | <create statement>
    | <export statement>
    | <call statement>
    | <expression statement>
<set statement> = <set body>
<reset statement> = <reset body>
<output statement> = <output body>
<create statement> = <create body>
<terminating statement> =
    <return statement>
    | <break statement>
    | <stop statement>
<variable definitions> = <variable definition statement>*
<variable definition statement> :: <local variables of sort>+
<local variables of sort> :: <aggregation kind> <variable<name>+ <sort> [<expression>]

```

## Transformations

```

<local variables of sort>(ak, varNames, s, expr) provided varNames.length > 1
=5=>
mk-<local variables of sort>(ak, < varNames.head >, s, expr) ^
if varNames.length > 1
then mk-<local variables of sort>(ak, varNames.tail, s, expr)
else empty
endif

```

A <local variables of sort> contains one or more several <variable<name> items. This is derived syntax for specifying a sequence of <local variables of sort> items, one for each <variable<name>. See clause 11.14.1 *Concrete grammar* of [ITU-T Z.102].

```

<variable definition statement>(varDefs) provided varDefs.length > 1
=5=>
mk-<variable definition statement>( < varDefs.head > ) ^
if varDefs.length > 1 then mk-<variable definition statement>( varDefs.tail ) else empty endif

```

A <variable definition statement> contains one or more <local variables of sort> items. This is derived syntax for specifying a sequence of <variable definition statement> items, one for each <local variables of sort>. See clause 11.14.1 *Concrete grammar* of [ITU-T Z.102].

## Mapping to abstract syntax

```

| <variable definition statement>( < var > ) then Mapping(var)

| <local variables of sort>(ak, < var >, s, expr) then
    mk-Variable-definition(Mapping(var), Mapping(s), Mapping(ak), Mapping(expr))

```

## F2.2.8.14.1 Compound statement

### Abstract syntax

<i>Compound-node</i>	::	<i>Connector-name</i> <i>Variable-definition-set</i> <i>Init-graph-node*</i> <i>While-graph-node</i> <i>Transition</i> <i>Step-graph-node*</i>
<i>Init-graph-node</i>	=	<i>Graph-node</i>
<i>While-graph-node</i>	=	<i>Expression*</i> [ <i>Finalization-node</i> ]
<i>Finalization-node</i>	=	<i>Graph-node</i>
<i>Step-graph-node</i>	=	<i>Graph-node</i>
<i>Continue-node</i>	::	<i>Connector-name</i>
<i>Break-node</i>	::	<i>Connector-name</i>

### Concrete syntax

<compound statement> :: [ <connector name> ] [ <variable definitions> ] <statements>

### Conditions on abstract syntax

$\forall cn \in \text{Continue-node}: \exists comp \in (\text{Compound-node}) :$   
 $isAncestorASI(comp, cn) \wedge (cn.s\text{-Connector-name} = comp.s\text{-Connector-name})$

A *Continue-node* shall be contained in a *Compound-node* that has been labelled with the given *Connector-name*.

$\forall bn \in \text{Break-node}: \exists comp \in (\text{Compound-node}) :$   
 $isAncestorASI(comp, bn) \wedge (bn.s\text{-Connector-name} = comp.s\text{-Connector-name})$

A *Break-node* shall be contained in a *Compound-node* that has been labelled with the given *Connector-name*.

### Transformations

<compound statement>(undefined, vardefs, stmts)  
=5=> **mk**-<compound statement>(newName, vardefs, stmts)

If the <compound statement> has a <connector name> this represents the *Connector-name*; otherwise a newly created anonymous name represents the *Connector-name*. See clause 11.14.1 *Concrete grammar* of [ITU-T Z.102].

*The following statements are handled by the Mapping.*

A <compound statement> creates its own scope for any variables defined in the statement and the connector name.

If the <compound statement> contains <variable definitions>, the following is performed for each <variable definition statement>. A new <variable name> is created for each <variable name> in the <variable definition statement>. Each occurrence of <variable name> in the following <variable definition statement>s and within <statements> is replaced by the corresponding newly created <variable name>.

For each <variable definition statement>, a <variable definition> is formed from the <variable definition statement> by omitting the initializing <expression> (if present) and inserted as a <variable definition statement> in place of the original <variable definition statement>. If an initializing <expression> is present, an <assignment statement> is constructed for each <variable name> mentioned in the <local variables of sort> in the order of their occurrence, where <variable name> is

given the result of <expression>. These <assignment statement> items are inserted at the front of <statement> items in the order of their occurrence.

If the <statements> list does not end in a <terminating statement>, the *Transition* is a *Graph-node* list represented by the <non terminating statements> of the <statements> list followed by a *Break-node* with the *Connector-name* as the *Terminator* of the *Transition*. If the <statements> list ends in a <terminating statement>, the *Transition* is a *Graph-node* list represented by the <non terminating statements> of the <statements> list followed by the *Terminator* represented by the <terminating statement>.

If the <statements> list is omitted, the *Transition* is an empty *Graph-node* list followed by a *Break-node* with the *Connector-name* as the *Terminator* of the *Transition*.

## Mapping to abstract syntax

```
| <compound statement>( cn, vars, allstats = stats  $\hat{}$  <laststatement >) then
  mk-Compound-node(Mapping(cn), Mapping(vars).toSet, undefined, empty,
    if laststatement  $\in$  <terminating statement>
    then mk-Transition(Mapping(stats), Mapping(laststatement))
    else mk-Transition(Mapping(allstats), mk-Break-node(Mapping(cn)))
  endif,
  empty)
```

```
| <compound statement>( cn, vars, empty) then
  mk-Compound-node(Mapping(cn), Mapping(vars).toSet, undefined, empty,
    mk-Transition(Mapping(empty), mk-Break-node(Mapping(cn))), empty)
```

### F2.2.8.14.2 Transition actions and terminators as statements

#### Concrete syntax

<assignment statement> :: <assignment>

<return statement> :: <return body>

<call statement> :: <procedure call body> | <remote procedure call body>

#### Conditions on concrete syntax

$\forall rs \in$  <return statement>:  
 (parentASOfKind(rs, <internal procedure definition>)  $\neq$  undefined)  $\vee$   
 (parentASOfKind(rs, <operation definition>)  $\neq$  undefined)

A <return statement> is only allowed within an <internal procedure definition> or within an <operation definition>.

#### Transformations

The following statements are handled by the Mapping.

<assignment statement> is transformed into the <task>

**task** <assignment>;

A <call statement> is derived syntax for <procedure call> and is transformed into a <procedure call> with the same <procedure call body>:

**call** <procedure call body>;

The transform of an <algorithm action statement> and a <return statement> is obtained by dropping the trailing <end>.

## Mapping to abstract syntax

```
| <assignment statement>(a) then Mapping(a)
```

```
| <return statement>(r) then Mapping(r)
```

| <call statement>(c) **then** Mapping(c)

### F2.2.8.14.3 Expressions as statements

#### Concrete syntax

<expression statement> :: <operator application>

#### Transformations

```
let nn=newName in
<expression statement>(expr) =3=>
  mk-<compound statement>(
    < mk-<variable definition statement>
      (<mk-<local variables of sort>( < nn >, expr.staticSort0, undefined) >) >,
    < mk-<assignment statement>( mk-<assignment>( mk-<identifier>(undefined, nn), expr)) >
  )
endlet // nn
```

A new <variable name> is created. A <variable definition> is constructed that declares the newly created <variable name> to be of the same sort as the result of <operation application>. Finally, the expression statement is transformed to a <compound statement> consisting of the newly constructed <variable definition>, followed by an <assignment> between the variable with <variable name> and the <operation application>.

### F2.2.8.14.4 If statements

#### Concrete syntax

```
<if statement> ::
  [<connector name>] <Boolean><expression> <consequence statement> [<alternative statement>]
<consequence statement> = [ <non terminating statement> ]
<alternative statement> = <non terminating statement> | <terminating statement>
<loop if statement> ::
  [<connector name>]
  <Boolean><expression> <loop consequence statement> [<loop alternative statement>]
<loop consequence statement> = [ <statement in loop> | <loop terminating statement>]
```

#### Transformations

```
<if statement>( connectorname, expr, cons, alt) =3=>
  mk-<decision statement>(connectorname, expr,
  mk-<decision statement body>(
    mk-<algorithm answer part>("true", cons),
    if alt ≠ undefined then mk-<algorithm else part>(alt) endif
  >, undefined))

<loop if statement>( connectorname, expr, cons, alt) =3=>
  mk-<loop decision statement>(connectorname, expr,
  mk-<decision statement body>(
    mk-<algorithm answer part>("true", cons),
    if alt ≠ undefined then mk-<algorithm else part>(alt) endif
  >, undefined))
```

The <if statement> (or <loop if statement>) is transformed to the following <decision statement> (or <loop decision statement> respectively):

```
decision boolean expression {
  ( true ): consequence statement
  else : alternative statement
};
```

where *boolean\_expression*, *consequence\_statement* and *alternative\_statement* represent actual text for the <Boolean expression>, <consequence statement> (<loop consequence statement> respectively) and <alternative statement> (<loop alternative statement> respectively).

### F2.2.8.14.5 Decision statements

#### Concrete syntax

```

<decision statement> ::
    [ <connector name> ] <question> <decision statement body>
    | <if statement>

<decision statement body> :: <algorithm answer part>+ [ <algorithm else part> ]

<algorithm answer part> :: <answer> [ <non terminating statement> | <terminating statement> ]

<algorithm else part> :: <alternative statement>

<loop decision statement> ::
    [ <connector name> ] <question> <loop decision statement body>
    | <loop if statement>

<loop decision statement body> :: <loop answer part>+ [ <loop else part> ]

<loop answer part> :: <answer> { <statement in loop> | <loop terminating statement> }

<loop else part> :: <loop alternative statement>

<loop alternative statement> = <statement in loop> | <loop terminating statement>

```

A <loop decision statement> differs from a <decision statement> only because it uses <loop decision statement body> instead of <decision statement body> (or <loop if statement> instead of <if statement>) so that <loop break statement> and <loop continue statement> are allowed in the loop. Similarly <loop answer part>, <loop else part>, <loop alternative statement>, <statement in loop> and <loop terminating statement> are used instead of <algorithm answer part>, <algorithm else part>, <alternative statement>, <non terminating statement> and <loop terminating statement>, respectively.

#### Mapping to abstract syntax

```

| <decision statement>( connectorname, ques, body) then
    Mapping(<loop decision statement>( connectorname, ques, body))

```

The main difference between a <decision statement> and a <loop decision statement> is the inclusion of <loop continue statement> and <loop break statement>, but these are syntactically excluded from <decision statement>, therefore the *Mapping* for <loop decision statement> is used here.

Each <algorithm answer part> of a <decision statement> represents a *Decision-answer* of the *Decision-node* of the *Transition* of the *Compound-node*. If the <algorithm answer part> is a <terminating statement>, the *Transition* of the *Decision-answer* is the *Terminator* represented by the <terminating statement>. If there is no <non terminating statement> or <terminating statement> in the <algorithm answer part>, the *Transition* of the *Decision-answer* is an empty *Graph-node* list followed by a *Break-node* with the *Connector-name* of the *Compound-node*. If the <algorithm answer part> is a <non terminating statement>, the *Transition* of the *Decision-answer* is the *Graph-node* represented by the <non terminating statement> followed by a *Break-node* with the *Connector-name* of the *Compound-node*.

An <algorithm else part> of a <decision statement> represents the *Else-answer* of the *Decision-node* of the *Transition* of the *Compound-node*. If the <alternative statement> is a <terminating statement>, the *Transition* of the *Else-answer* is the *Terminator* represented by the <terminating statement>. If there is no <alternative statement> or no <algorithm else part> in the <decision statement> the *Transition* of the *Else-answer* contains only a *Break-node* with the *Connector-name* of the *Compound-node*. If the <alternative statement> is a <non terminating statement>, the *Transition* of the *Else-answer* is the *Graph-node* represented by the <non terminating statement>.

The mapping of <algorithm answer part> and <algorithm else part> is included in the mapping of <decision statement>. The <if statement> alternative of <decision statement> is removed by a transformation in F2.2.8.14.4 If statements.

```

| <loop decision statement>( connectorname, ques, <loop decision statement body>(answers, elsePart)) then
  let cn= if connectorname = undefined then newName else connectorname endif in
    mk-Compound-node(Mapping(cn), Ø, empty,
      mk-Transition(
        mk-Decision-node(
          mk-Decision-body(
            Mapping(ques),
            { mk-Decision-answer(
              Mapping(ans),
              if stat(cc) ∈ <loop continue statement>
                then mk-Transition(empty,
                  if cc = undefined
                    then mk-Continue-node(cn)
                    else mk-Continue-node(cc)
                  endif)
              elseif stat ∈ <loop terminating statement>
                then mk-Transition(empty, Mapping(stat))
              elseif stat = undefined
                then mk-Transition(empty, mk-Break-node(cn))
                else mk-Transition(Mapping(stat), mk-Break-node(cn))
              endif)
            | <algorithm answer part>(ans, stat) in answers },
          mk-Else-answer(
            if elsePart ∈ <loop terminating statement>
              then mk-Transition(empty, Mapping(elsePart))
            elseif elsePart = undefined
              then mk-Transition(empty, mk-Break-node(cn))
            else mk-Transition(Mapping(elsePart), mk-Break-node(cn))
            endif)
        )
      )
    )
  )
)
endlet

```

A <loop decision statement> represents a *Compound-node* in the same way as <decision statement> except that a *Transition* of a *Decision-answer* or *Else-answer* has a *Break-node* for a <loop break statement> or a *Continue-node* for a <loop continue statement>. The mapping of <loop answer part> and <loop else part> is included in the mapping of <loop decision statement>. The <loop if statement> alternative of <loop decision statement> is removed by a transformation in F2.2.8.14.4 If statements.

### F2.2.8.14.6 Loop statements

#### Concrete syntax

```

<loop statement> ::
    [ <connector name> ] <loop clause>* <loop body statement> [<finalization statement>]

<loop body statement> = <statement in loop>

<statement in loop> =
    <statement>
    | <loop statement>
    | <loop compound statement>
    | <loop decision statement>

<loop compound statement> ::
    [ <connector name> ] <variable definitions> <loop statements>

```

A <loop compound statement> differs from a <compound statement> because it uses <loop statements> instead of <statements>.

```
<loop statements> ::
    <statement in loop>+ [ <loop terminating statement> ]
    | <loop terminating statement>
```

A <loop statements> list differs from a <statements> because it optionally ends with a <loop terminating statement> instead of <terminating statement>, and also because it has <statement in loop> instead of <statement>.

```
<loop terminating statement> =
    <terminating statement>
    | <loop break statement>
    | <loop continue statement>
```

A <loop terminating statement> allows <loop break statement> and <loop continue statement> as well as <terminating statement>.

```
<finalization statement> = <statement> | <compound statement>
<loop clause> ::
    [<loop variable indication>] [<Boolean<expression>] <loop step>
<loop step> = [<expression>]
<loop variable indication> =
    <loop variable definition> | <loop variable indication identifier>
<loop variable indication identifier> :: <variable<identifier> [<expression>]
<loop variable definition> :: <aggregation kind> <variable<name> <sort> <expression>
<loop break statement> :: ()
<loop continue statement> :: [<connector<name>]
```

### Conditions on concrete syntax

```
∀lvii ∈ <loop variable indication identifier>:
    getEntityDefinition0(lvii.s-<identifier>, variable) ∉ <loop variable definition>
```

A <variable<identifier> of a <loop variable indication> shall not identify a variable defined in a <loop variable definition>. See clause 11.14.1 *Concrete grammar* of [ITU-T Z.102].

```
∀lc ∈ <loop clause>:
    if = lc.s-<loop step> ∈ <expression> then
    then lc.s-<loop variable indication> ≠ undefined
    endif
```

If a <loop step> of a <loop clause> has an <expression> the <loop variable indication> of the <loop clause> shall not be omitted. See clause 11.14.1 *Concrete grammar* of [ITU-T Z.102].

```
∀ as ∈ <assignment>:
    let ls = parentAS0ofKind(as, <loop statement>) in // containing loop statement
    let avid = as.s1.variableId0 in // assignment variable id
    ls = undefined
    ∨
    ( ¬ (∃ lvii ∈ <loop variable indication identifier>: lvii.s-<identifier> = avid ∧ isAncestorAS0)(ls, lvii))
    ∧
    ¬ (∃ lvd ∈ <loop variable definition>: lvd = getEntityDefinition0(avid, variable) ∧ isAncestorAS0)(ls, lvd))
    )
```

There shall be no assignments to a loop variable in the <loop body statement>. See clause 11.14.1 *Concrete grammar* of [ITU-T Z.102].

## Transformations

$l = \langle \text{loop statement} \rangle \wedge l.s - \langle \text{connector name} \rangle = \text{undefined} \Rightarrow$   
 $l.s - \langle \text{connector name} \rangle = \text{newName}$

Generate a name for every unlabelled  $\langle \text{loop statement} \rangle$ .

## Mapping to abstract syntax

```
|  $l = \langle \text{loop statement} \rangle (cn, lc, body, final)$  then
  mk-Compound-node(Mapping(cn),
    // Variable-definition-set of the Compound-node
    { mk-Variable-definition(
      Mapping(c.s- $\langle \text{loop variable indication} \rangle$ .s- $\langle \text{name} \rangle$ ),
      Mapping(c.s- $\langle \text{loop variable indication} \rangle$ .s- $\langle \text{sort} \rangle$ ),
      PART,
      undefined) // Variable definition
      |  $c \in lc.toSet \wedge c.s - \langle \text{loop variable indication} \rangle \in \langle \text{loop variable definition} \rangle$ 
    }, // Variable-definition-set of the Compound-node
    // Init-graph-node list of the Compound-node
    < let  $lvi = lc.s - \langle \text{loop variable indication} \rangle$  in
      if  $lvi \in \langle \text{loop variable definition} \rangle$ 
      then mk-Graph-node(mk-Task-node(
        mk-Assignment(
          Mapping(mk- $\langle \text{identifier} \rangle$ (mk- $\langle \text{path item} \rangle$ (composition, cn) >,  $lvi.s - \langle \text{name} \rangle$ )),
          Mapping( $lvi.s - \langle \text{expression} \rangle$ ))
        ))
      elseif //  $lvi \in \langle \text{loop variable definition indicator} \rangle$ 
         $lvi.s - \langle \text{expression} \rangle \neq \text{undefined}$ 
      then mk-Graph-node(mk-Task-node(
        mk-Assignment(Mapping( $lvi.s - \langle \text{identifier} \rangle$ ), Mapping( $lvi.s - \langle \text{expression} \rangle$ )))
        ))
      endif
      endlet //  $lvi$ 
    |  $c$  in  $lc$ :  $c.s - \langle \text{loop variable indication} \rangle \neq \text{undefined}$  >,

    mk-While-graph-node(
      < mk-Expression( $c.s - \langle \text{expression} \rangle$ ) |  $c$  in  $lc$ :  $c.s - \langle \text{expression} \rangle \neq \text{undefined}$  >,
      // Finalization-node of the Compound-node
      if  $final \neq \text{undefined}$  then mk-Graph-node(Mapping( $final$ )) endif
    ),
    // Transition of the Compound-node
    if  $body(cc) \in \langle \text{loop continue statement} \rangle$ 
    then mk-Transition(empty,
      if  $cc = \text{undefined}$ 
      then mk-Continue-node(Mapping(cn))
      else mk-Continue-node(Mapping(cc))
      endif)
    elseif  $body \in \langle \text{loop terminating statement} \rangle$ 
    then mk-Transition(empty, Mapping( $body$ ))
    elseif  $body = \text{undefined}$ 
    then mk-Transition(empty, mk-Continue-node(Mapping(cn)))
    else mk-Transition(< Mapping( $body$ ) >, mk-Continue-node(Mapping(cn)))
    endif,
    // Step-graph-node of the Compound-node
    < let  $lvi = c.s - \langle \text{loop variable indication} \rangle$  in
      let  $ls = c.s - \langle \text{loop step} \rangle$  in
      if  $lvi \in \langle \text{loop variable definition} \rangle$ 
      then mk-Graph-node(mk-Task-node(
        mk-Assignment(
          Mapping(mk- $\langle \text{identifier} \rangle$ (mk- $\langle \text{path item} \rangle$ (composition, cn) >,  $lvi.s - \langle \text{name} \rangle$ )),
          Mapping( $ls$ ))
        ))
      </pre>

```

```

    ))
    else mk-Graph-node(mk-Task-node(
        mk-Assignment(Mapping(lvi.s-<identifier>), Mapping(ls))
    ))
    endif
    endlet // ls
    endlet // lvi
    | c in lc: c.s-<loop step> ≠ undefined >
) // end of Compound-node for <loop statement>

```

A <loop statement> represents a *Compound-node*. If the <loop statement> has a <connector name> this represents the *Connector-name*; otherwise a newly created anonymous name represents the *Connector-name*.

Each <aggregation kind> <variable name> <sort> set in a <loop variable definition> represents the *Aggregation-kind*, *Variable-name* and *Sort-reference-identifier* of an element of the *Variable-definition-set* of the *Compound-node*. Each <variable name> and associated <expression> in a <loop variable definition> also represents the *Variable-identifier* and *Expression* of an *Assignment* in a *Task-node* of the *Init-graph-node* list of the *Compound-node*. The <variable name> in a <loop variable definition> also represents the *Variable-identifier* in any *Step-graph-node* for the <loop step> following the <loop variable indication>.

Each <variable identifier> and associated <expression> in a <loop variable indication> represents the *Variable-identifier* and *Expression* of an *Assignment* in a *Task-node* of the *Init-graph-node* list of the *Compound-node*. The <variable identifier> in a <loop variable indication> also represents the *Variable-identifier* in the *Step-graph-node* for the <loop step> following the <loop variable indication>. The <variable identifier> in the <loop variable indication> also represents the *Variable-identifier* in any *Step-graph-node* for the <loop step> following the <loop variable indication>.

The *Task-node* items from the <loop variable indication> items occur in the *Init-graph-node* list in the same order (left to right, top to bottom) as the <loop clause> items in the <loop statement>.

Each <Boolean expression> in a <loop clause> represents a Boolean *Expression* in the *While-graph-node* of the *Compound-node* for the <loop statement> in the order of each <loop clause> in the <loop statement>.

A <loop body statement> represents the *Transition* of the *Compound-node*. The *Transition* is the *Graph-node* represented by the <statement in loop> (a <non terminating statement> or <loop statement> or <loop compound statement> or <loop decision statement>) followed by a *Continue-node* with the *Connector-name* of the *Compound-node*.

Each <expression> of a <loop step> represents an *Expression* of an *Assignment* in a *Task-node* of the *Step-graph-node* list of the *Compound-node*. The *Variable-identifier* of the *Assignment* is the one represented by the <variable identifier> or <variable name> of the preceding <loop variable indication>.

The *Task-node* items from the <loop step> items occur in the *Step-graph-node* list in the same order (left to right, top to bottom) as the <loop clause> items in the <loop statement>.

The mapping of <finalization statement>, <loop clause>, <loop step>, <loop variable indication>, <loop variable indication identifier> and <loop variable definition> is included in the mapping of <loop statement>.

```

| <loop compound statement>( cn, vars, allstats = stats ^ <laststatement> ) then
    mk-Compound-node(Mapping(cn), Mapping(vars).toSet, undefined, empty,
        if laststatement ∈ <loop terminating statement>
            then mk-Transition(Mapping(stats), Mapping(laststatement))
            else mk-Transition(Mapping(allstats), mk-Break-node(Mapping(cn)))
        endif,
        empty)

```

A <loop compound statement> represents a *Compound-node* in the same way as a <compound statement> except that the *Transition* represented by <loop statements> optionally ends with a *Break-node* for a <loop break statement> or a *Continue-node* for a <loop continue statement>.

```
| lbs = <loop break statement> then
  mk-Break-node(Mapping(parentASOfKind(lbs, <loop statement>).s-<connector name>))
```

A <loop break statement> represents a *Break-node* with the *Connector-name* of the immediately enclosing *Compound-node* for a <loop statement>.

```
| lcs = <loop continue statement>(cn) then
  if cn = undefined
  then mk-Continue-node(Mapping(parentASOfKind(lcs, <loop statement>).s-<connector name>))
  else mk-Continue-node(Mapping(cn))
  endif,
```

A <loop continue statement> without a <connector name> represents a *Continue-node* with the *Connector-name* of the immediately enclosing *Compound-node* for a <loop statement>. A <connector name> in a <loop continue statement> represents the *Connector-name* of the *Continue-node*.

### Auxiliary functions

The function *variableId0* returns the identifier of the variable for the left hand side of an assignment. If the variable is an <indexed variable> or a <field variable>, the composite variable that contains the indexed or field element is returned.

```
variableId0(v:<identifier> ∪ <indexed variable> ∪ <indexed variable>): <identifier> =def
  case v of
  | <identifier> then v
  | <indexed variable> then v.s1-implicit
  | <field variable> then v.s1-implicit
  endcase
```

### F2.2.8.14.7 Break statement

#### Conditions on abstract syntax

$$\forall bs \in \text{Break-node}: \exists ls \in (\text{Compound-node}):$$

$$isAncestorASI(ls, bs) \wedge (bs.s\text{-Connector-name} = ls.s\text{-Connector-name})$$

A *Break-node* shall be contained in a *Compound-node* that has been labelled with the given *Connector-name*.

#### Concrete syntax

```
<break statement> :: <connector><name>
```

#### Mapping to abstract syntax

```
| <break statement>(name) then mk-Break-node(Mapping(name))
```

### F2.2.8.15 Timer

#### Abstract syntax

```
Timer-definition           :: Timer-name
                               Sort-reference-identifier*
                               [ Timer-default-initialization ]

Timer-default-initialization = Constant-expression

Set-node                   :: Time-expression Timer-identifier Expression*

Time-expression           = Expression

Reset-node                 :: Timer-identifier Expression*
```

## Conditions on abstract syntax

$\forall n \in \text{Set-node} \cup \text{Reset-node}: \forall d \in \text{Timer-definition}:$   
( $d = \text{getEntityDefinition1}(n.s\text{-Timer-identifier}, \text{timer}) \Rightarrow$   
 $\text{isActualAndFormalParameterMatched1}(n.s\text{-Expression-Seq}, d.\text{formalParameterSortList1})$ )

The sorts of the *Expression* list in the *Set-node* and *Reset-node* shall correspond by position to the list of *Sort-reference-identifier* list directly following the *Timer-name* in the *Timer-definition* identified by the *Timer-identifier*. See clause 11.15 *Abstract grammar* of [ITU-T Z.101].

## Concrete syntax

<timer definition> :: <timer definition item>+  
<timer definition item> ::  
    <timer<name> [ <sort list> ] [<timer default initialization>]  
<timer default initialization> :: <Duration><constant expression>  
<set> :: <set body>  
<set body> :: <set clause>+  
<set clause> :: [ <Time><expression> ] <timer<identifier> <expression>\*  
<reset> :: <reset body>  
<reset body> :: <reset clause>+  
<reset clause> :: <timer<identifier> <expression>\*

## Transformations

<set clause>(undefined, id, exprList)  
=8=>  
**mk**-<set clause>(mk-<operator application>(  
    **mk**-<operator identifier>(predefinedQual0("Time"), ""+""""),  
    **now**,  
    id.refersto0.s-<timer default initialization>),  
id, exprList)

A <set clause> with no <Time expression> is derived syntax for a <set clause> where <Time expression> is

**now** + <Duration constant expression>

where <Duration constant expression> is derived from the <timer default initialization> in timer definition.

<set>( <set body>( <s> ^ rest)) **provided** rest ≠ empty =5=>  
**mk**-<set>(mk-<set body>( <s>)) ^ **mk**-<set>((mk-<set body>(rest))

A <set> is allowed to contain several <set clause> items. This is derived syntax for specifying a sequence of <set> items, one for each <set clause> such that the original order in which they were specified in the <set> is retained.

<set statement>( <set body>( <s> ^ rest)) **provided** rest ≠ empty =5=>  
**mk**-<set statement>(mk-<set body>( <s>)) ^ **mk**-<set statement>((mk-<set body>(rest))

A <set statement> is allowed to contain several <set clause> items. This is derived syntax for specifying a sequence of <set statement> items, one for each <set clause> such that the original order in which they were specified in the <set> is retained.

<reset>( <reset body>( <r> ^ rest)) **provided** rest ≠ empty =5=>  
**mk**-<reset>(mk-<set body>( <r>)) ^ **mk**-<reset>(mk-<set body>(rest)) >

A <reset> is allowed to contain several <reset clause> items. This is derived syntax for specifying a sequence of <reset> items, one for each <reset clause> such that the original order in which they were specified in the <reset> is retained.

```
<reset statement>(<reset body>(< s > ^ rest)) provided rest ≠ empty =5=>
  mk-<reset statement>(mk-<reset body>(< s >)) ^ mk-<reset statement>((mk-<reset body>)(rest))
```

A <reset statement> is allowed to contain several <reset clause> items. This is derived syntax for specifying a sequence of <reset statement> items, one for each <reset clause> such that the original order in which they were specified in the <reset> is retained.

The shorthand items for <set>, <set statement>, <reset> and <reset statement> are expanded before shorthand items in the contained expressions are expanded. The shorthand items are in clause 11.5 *Model* of [ITU-T Z.103].

```
<timer definition>(< t > ^ rest) provided rest ≠ empty =5=>
  mk-<timer definition>(< t >) ^ mk-<timer definition>(rest)
```

A <timer definition> is allowed to contain several <timer definition item>s. This is derived syntax for specifying a sequence of <timer definitions>s, one for each <timer definition item>. See clause 11.5 *Model* of [ITU-T Z.103].

## Mapping to abstract syntax

```
| <timer definition>(< item >) then Mapping(item)
| <timer definition item>(name, sortList, *) then
  mk-Timer-definition(Mapping(name), Mapping(sortList))
| <set>(< clause >) then mk-Graph-node(Mapping(clause))
| <set clause>(expr, id, params) then mk-Set-node(Mapping(expr), Mapping(id), Mapping(params))
| <reset>(< clause >) then mk-Graph-node(Mapping(clause))
| <reset clause>(id, params) then mk-Reset-node(Mapping(id), Mapping(params))
```

## F2.2.9 Data

### F2.2.9.1 Data definitions

#### Concrete syntax

```
<data definition> =
  <entity in data type> | <interface definition>
<sort> ::
  <basic sort> [ <range condition> ]
  | <anchored sort>
  | <pid sort>
  | <inline data type definition>
  | <inline syntype definition>
<basic sort> =
  <datatype><type expression>
  | <as signal>
  | <as interface>
  | <as channel>
  | <as gate>
  | <syntype>
<anchored sort> :: { this | parent } [ <basic sort> ]
<pid sort> = <sort><identifier>
```

<inline data type definition> :: [ <data type specialization> ] <data type definition body>  
 <inline syntype definition> :: <basic sort> { <default initialization> [<constraint> ] | <constraint> }

## Conditions on concrete syntax

```

 $\forall s \in \langle \text{sort} \rangle$ :
  ( $\forall bsd = \text{getEntityDefinition0}(s.s-\langle \text{basic sort} \rangle.s-\langle \text{identifier} \rangle, \mathbf{sort})$ :  $s.s-\langle \text{basic sort} \rangle \in \langle \text{type expression} \rangle$ )
  ^
  ( $\forall rc = s.s-\langle \text{range condition} \rangle$ : ( $rc \neq \text{undefined}$ ))
  =>
     $bsd.s-\langle \text{data type definition body} \rangle.s\text{-implicit} \in \langle \text{literal list} \rangle$ 
  v  $\text{isSizeConstraintValid}(bs)$ 

```

A <range condition> after a <basic sort> of a sort is only valid if the <basic sort> has been constructed using the literal data type constructor and the **constants** (<range condition>) is valid as a <constraint> for the <basic sort>, or if the **size** (<range condition>) is valid as a <constraint> for the <basic sort>. See clause 12.1 *Concrete grammar* of [ITU-T Z.104].

## Transformations

```

s = <anchored sort>(*, undefined)
=14=>
mk-< sort>(
  mk-<type expression>(sortId0(s),empty),
  undefined) // range condition omitted

```

An <anchored sort> without a <basic sort> is a shorthand for specifying a <basic sort> with the name of the data type definition (or syntype definition) in the context where the <anchored sort> occurs. See clause 12.1 *Model* of [ITU-T Z.104].

Every occurrence of an <anchored sort> of the form **parent** T in a specialization of T, the <anchored sort> is replaced by an unambiguous qualified <basic sort> for the base type T: that is, the qualified <identifier> for T. Every occurrence of an <anchored sort> of the form **this** T in a specialization of T, the <anchored sort> is replaced by the <basic sort> of the subsort: that is, the <identifier> for the subsort ST. See clause 12.1.9 *Model* of [ITU-T Z.104].

```

let nn = newName in
s = <sort>(<type expression>(bsort, empty), rc)
=8=>
mk-< sort>(mk-<syntype-identifier>(s.surroundingScopeUnit0.fullQualifierWithin0, nn),undefined)
and // add the implicit syntype definition
=>
let parent = s.surroundingScopeUnit0 in entities=parent.getEntities0 in
entities ^
mk-<syntype definition>(empty,
  mk-<syntype definition syntype>(nn,
    bsort,
    undefined,
    if getEntityDefinition0(bsort, sort).s-<data type definition body>.s-implicit ∈ <literal list>
    then rc
    else mk-<size constraint>(rc)
  endif
) )
endlet // parent
endlet // nn

```

A <sort> that is a <basic sort> with a <range condition> is derived concrete syntax for a <syntype> of an implied <syntype definition> having an anonymous name for the <syntype name> and the <basic sort> as the <parent sort identifier>. This anonymously named <syntype definition> is defined with no <default initialization> and with its elements restricted by a <constraint> based on the <range condition>. If the <basic sort> has been constructed using the literal data type constructor the <range

condition> is transformed to a <constraint> of the <syntype definition> that is **constants** (<range condition>); otherwise, the <range condition> is transformed to a <constraint> of the <syntype definition> that is **size** (<range condition>). See clause 12.1 *Model* of [ITU-T Z.104].

NOTE – The conditions on concrete syntax described below (in clause F2.2.9.8.4, Constraint) apply to the <syntype> and its <constraint> based respectively on <basic sort> and <range condition>.

```

let nn = newName in
s = <inline data type definition>(dtspecial, dtbody)
=2=>
let parent = s.surroundingScopeUnit0 in
mk-<type expression>( mk-<identifier>( parent.fullQualifierWithin0,nn), empty)
and // add the implicit data type definition
entities=parent.getEntities0
=>
entities ^ mk-<data type definition>(empty, undefined, nn, dtspecial, dtbody, undefined)
endlet // parent
endlet // nn

```

An <inline data type definition> is derived concrete syntax for a <basic sort> of an implied <data type definition> having an anonymous name. This anonymously named <data type definition> is derived from the <inline data type definition> by inserting **type** and the anonymous name after **value** in the <inline data type definition>. Each <inline data type definition> defines a different implied <data type definition>. See clause 12.1 *Model* of [ITU-T Z.104].

```

<inline syntype definition>(bsort, x )
=2=>
case x of
| <default initialization> then mk-<inline syntype definition>(bsort, x, undefined)
| <constraint> then mk-<inline syntype definition>(bsort, undefined, x)
endcase

let nn = newName in
s = <inline syntype definition>(bsort, init, constr)
=2=>
mk-<syntype><identifier>( s.surroundingScopeUnit0.fullQualifierWithin0, nn)>
and // add the implicit syntype definition
let parent = s.surroundingScopeUnit0 in
entities=parent.getEntities0
=>
entities ^ mk-<syntype definition>(empty, mk-<syntype definition syntype>(nn, bsort, init, constr))
endlet // parent
endlet // nn

```

An <inline syntype definition> is derived concrete syntax for a <basic sort> of an implied <syntype definition> having an anonymous name. This anonymously named <syntype definition> is derived from the <inline syntype definition> by inserting the anonymous name and <equals sign> after syntype in the <inline syntype definition>. See clause 12.1 *Model* of [ITU-T Z.104].

### Auxiliary functions

The function *sortId0* gets the <identifier> of a <sort>. Any <inline data type definition> or <inline syntype definition> is replaced at transformation step 2 by a <basic sort> or <syntype> (respectively), therefore these would not be offered as a parameter to *sortId0*.

```

sortId0(s: <sort>): <identifier> =def
case s of
| <type expression> then s.s-<identifier> // base type of type expression –actual context params ignored
| <as signal>(sigId) then sigId.asSignal
| <as interface>(ifid) then
  if ifid.refersto0.asInterfaceName ≠ undefined

```

```

    then mk-<type expression>(
      mk-<identifier>(ifid.s-<qualifier>, ifid.refersto0.asInterfaceName), undefined)
    else undefined
  endif
| <as channel>(cid) then
  if cid.refersto0.asChannelName ≠ undefined
  then mk-<type expression>(
    mk-<identifier>(cid.s-<qualifier>, cid.refersto0.asChannelName), undefined)
  else undefined
  endif
| <as gate>(gid) then
  if gid.refersto0.asGateName ≠ undefined
  then mk-<type expression>(mk-<identifier>(gid.s-<qualifier>, gid.refersto0.asGateName), undefined)
  else undefined
  endif
| anchSort = <anchored sort> then
  let parentDataTypeDef = parentAS0ofKind(anchSort, <data type definition>) in
  let basicSort = anchSort.s-<type expression>.s-<identifier> in
  case anchSort.s-implicit of
  | this then
    if basicSort = undefined ∨ isSubSort0(basicSort, parentDataTypeDef.identifier0)
    then parentDataTypeDef.identifier0 // change to subsort id if basic sort undefined or supersort
    else basicSort // otherwise specified basic sort id
    endif
  | parent then
    if basicSort = undefined
    then // if basic sort undefined
      if parentDataTypeDef.specialization0 ≠ undefined // if a specialized sort
      then parentDataTypeDef.specialization0.s-<type expression>.s-<identifier> // sort id of supersort
      else parentDataTypeDef.identifier0 // otherwise the sort id of the enclosing data type
      endif
    elseif isSubSort0(basicSort, parentDataTypeDef.identifier0) // basic sort defined and supersort
    then basicSort // if enclosing data type subsort of basic sort, change to basic sort id
    else parentDataTypeDef.identifier0 // otherwise the sort of the enclosing data type
    endif
  endcase
  endlet // basicSort
  endlet // parentDataTypeDef
| <identifier> then s.s-<identifier> // pid sort or syntype
| <inline data type definition> then undefined // replaced at step 2 by <basic sort> or <syntype>
| inlsd = <inline syntype definition> then inlsd.s-<basic sort>.sortId0
otherwise undefined
endcase

```

The function *isSizeConstraintValid* determines if the range condition is a valid size constraint for the data type definition.

A <size constraint> shall only be used in the concrete syntax of a <constraint> if Length has been defined as an operation with the <operation signature>:

```
length (in P) -> <<package Predefined>>Integer;
```

Where P is the sort of the syntype for the context of the <constraint>. See clause 12.1.8.2 *Concrete grammar* of [ITU-T Z.101].

```

isSizeConstraintValid(dtd: <data type definition>): BOOLEAN =def
(∃ opSig ∈ <operation signature>:
  opSig.s-<name> = mk-<name>("length")
  ∧ opSig.s-<arguments>.length = 1
  ∧ opSig.s-<arguments>[1].s-<formal parameter> =
    mk-<formal parameter> (in, mk-<sort>(mk-<type expression>(dtd.identifier0,empty)))
  ∧ opSig.s-<result> = mk-<sort>(mk-<type expression>( predefinedId0("Integer"),empty)
)

```

## F2.2.9.2 Data type definition

### Abstract syntax

*Data-type-definition* = *Value-data-type-definition*  
| *Interface-definition*

*Value-data-type-definition* :: *Sort*  
[ *Data-type-identifier* ]  
*Literal-signature-set*  
*Null-literal-signature*  
*Static-operation-signature-set*  
*Dynamic-operation-signature-set*  
*Procedure-definition-set*  
*Data-type-definition-set*  
*Syntype-definition-set*  
*Variable-definition-set*  
[ *Default-initialization* ]  
[ *Abstract* ]

### Concrete syntax

<data type definition> ::  
  <package use clause>\* <type preamble> <data type heading> [<data type specialization>]  
  [ <data type definition body> ]

<data type heading> ::  
  <data type name> [ <formal context parameters> ] [<virtuality constraint>]

<data type definition body> ::  
  <entity in data type>\* [<data type constructor>] <operations> [<default initialization>]

<entity in data type> =  
  <data type definition> | <syntype definition> | <synonym definition>

<operations> :: <operation signatures> <operation definitions>

<operation definitions> :: <operation definition item>\*

### Conditions on concrete syntax

$\forall dtd \in \langle \text{data type definition} \rangle: \forall fcp \in \langle \text{formal context parameter} \rangle:$   
 $fcp \in dtd.localFormalContextParameterList0.toSet \Rightarrow$   
 $fcp \in \langle \text{sort context parameter} \rangle \cup \langle \text{synonym context parameter list} \rangle$

A <formal context parameter> of <formal context parameters> of a <data type heading> or <legacy data type definition> shall be either a <sort context parameter> or a <synonym context parameter list>. See clause 12.1.1 *Concrete grammar* of [ITU-T Z.104].

$\forall anchSort \in \langle \text{anchored sort} \rangle:$   
 $parentAS0ofKind(anchSort, \langle \text{data type definition} \rangle) \neq \text{undefined}$

An <anchored sort> is legal concrete syntax only if it occurs within a <data type definition>. The <basic sort> in the <anchored sort> shall name the <sort> introduced by an enclosing <data type definition>. See clause 12.1 *Model* of [ITU-T Z.104].

$\forall sid \in \langle \text{pid sort} \rangle: isPidSort0(sid)$

The <sort identifier> in a <pid sort> shall identify a pid sort. See clause 12.1 *Concrete grammar* of [ITU-T Z.101].

### Mapping to abstract syntax

| *dtd* = <data type definition>(\*, // package use clause

otherwise
  { Mapping(entities[i]) | i ∈ 1.. entities.length } ∪ Mapping(operations) // ctor is undefined
endcase

```

The parameter *ctor* of the <data type definition body> is an optional <data type constructor>, which is a <literal list>, a <structure definition> or a <choice definition>.

```

| <operations>( operationsignatures, operationdefinitions)
then
  Mapping(operationsignatures) ∪ Mapping(operationdefinitions)

| <operation definitions>( operationdefinitionitems)
then
  { Mapping(operationdefinitionitems[i]) | i ∈ 1..operationdefinitionitems.length }

```

The following paragraphs are from clause 12.1.2 *Concrete grammar* of [ITU-T Z.101], and appear here because they are concerned with implicit *Interface-definition* items added to *Data-type-definition* sets.

Each agent type (and agent and state machine) implicitly defines an *Interface-definition*. This *Interface-definition* is in the same context as the definition of the agent type (or agent or state machine), so that (for example) the implicit *Interface-definition* for an item of the *Agent-type-definition-set* of an *Agent-type-definition* is an item of the *Data-type-definition-set* of the *Agent-type-definition*.

Interfaces are implicitly defined by each agent type definition and each agent definition (except the outermost agent) and by the state machine of each agent type definition. The implicitly defined interface for an agent or an agent type has the same name and is defined in the same scope unit as the agent or agent type that defined it. The implicitly defined interface for a state machine has the same name as the containing agent type but is defined in the same scope unit as the state machine that defined it: that is, inside the agent type.

An <interface name> represents the *Sort* of the *Interface-definition*, and this <name> is the *Interface-qualifier* as the <name> of a <path item> for a <qualifier> to identify the *Interface-definition* as a scope unit.

A <signal list> of an <interface use list> denotes items in the *Signal-identifier-set* of the *Interface-definition* as follows.

- a) Each <signal identifier> of a <signal list> of an <interface use list> represents a corresponding *Signal-identifier* in the *Signal-identifier-set* that identifies a *Signal-definition*.
- b) Each <timer identifier> of a <signal list> of an <interface use list> represents a corresponding *Signal-identifier* in the *Signal-identifier-set* that identifies a *Timer-definition*.
- c) Each <interface identifier> of a <signal list> of an <interface use list> represents corresponding *Signal-identifier* items in the *Signal-identifier-set*: one for each *Signal-definition* of *Signal-definition-set* of the identified *Interface-definition*.
- d) Each *Signal-identifier* in the *Signal-identifier-set* appears only once, even if it corresponds to more than one item in the <signal list> of an <interface use list>.

The defining context of entities defined in the interface (<entity in interface>) is the scope unit of the interface, and the entities defined are visible where the interface is visible.

The following paragraphs are from clause 12.1.2 *Semantics* of [ITU-T Z.101].

The *Sort* of an *Interface-definition* is a pid sort. Each element of the *Sort* is the identity of an agent instance that is able to receive each of the signals identified by the *Signal-identifier-set* of the *Interface-definition*.

The *Null-literal-signature* of an *Interface-definition* is the signature for the null literal operator.

The *Data-type-identifier* set of an *Interface-definition* identifies the base interface types (super types) of an interface specialization. *Pid* is directly or indirectly the base interface types of any *Interface-definition* for a pid sort.

The *Signal-identifier-set* of an *Interface-definition* identifies signals defined outside the interface that are used by the interface and also each signal defined by a *Signal-definition* of the *Interface-definition*.

The *Signal-definition-set* of an *Interface-definition* is the set of signals defined for the interface. The scope of the signals is such that they are visible wherever the interface is visible. These signals are included in the *Signal-identifier-set* of the *Interface-definition*.

The *Signal-identifier-set* of an *Interface-definition* is the set of signal identities that apply when the interface appears in the syntax, and the set of signal identities for the pid sort of the *Interface-definition*. An identity of an agent instance is compatible with the pid sort if every *Signal-identifier* set of the pid sort is in the valid input signal set of the agent.

The implicit *Interface-definition* for an agent type (or agent or state machine) has a *Sort* with the same *Name* as the agent type (or agent or state machine respectively).

Internally connected gates of an agent type are gates of the agent type that are connected via channels to the gates of either a contained agent or the state machine of the agent type. The internally connected gates of an agent are the gates of the agent that correspond to the internally connected gates of the agent type for the agent.

The implicit *Interface-definition* defined by an agent type contains (in its interface specialization – see [ITU-T Z.104]) all interfaces given in the incoming signal lists associated with internally connected gates. The *Interface-definition* contains in its *Signal-identifier-set* all signals given in the incoming signal lists associated with internally connected gates.

The implicit *Interface-definition* defined by a state machine of an agent type contains (in its interface specialization – see [ITU-T Z.104]) the interface defined by the agent type itself except any part of that interface concerned only with contained agents. The interface also contains in its interface specialization all interfaces given in the incoming signal lists associated with any gates of the state machine. The interface also contains in its <interface use list> all signals given in the incoming signal lists associated with gates of the state machine.

The *Signal-identifier-set* of an implicit *Interface-definition* for an agent type (or agent or state machine) has a *Signal-identifier* for each different signal in the set of signals in all channels or gates for which the destination is the agent type (or agent or state machine respectively), plus the valid input signal set defined explicitly for the agent type (or agent or state machine respectively).

The implicit *Interface-definition* of a typebased agent contains the same *Signal-identifier-set* as the *Interface-definition* defined by its type.

NOTE – Because every agent and agent type has an implicitly defined interface with the same name, any explicitly defined interface has to have a different name from every agent and agent type defined in the same scope; otherwise, there are name clashes.

The following paragraph is from clause 12.1.2 *Concrete grammar* of [ITU-T Z.104].

An <interface definition> (or implicit interface definition) defines a *Data-type-definition* of a choice data type with a unique anonymous *Sort* name in the context that the *Interface-definition* is visible. A <basic sort> that is <as interface> where <interface identifier> identifies the *Interface-definition*, represents this *Data-type-definition*. The *Data-type-definition* is equivalent to defining a choice data

type with a <choice of sort> for each distinct *Signal-definition* identified by the *Signal-identifier-set* of the *Interface-definition*. The <field name> and <field sort> for each <choice of sort> is determined in the same way as a <choice of sort> for each distinct *Signal-definition* of the *Data-type-definition* defined by a <gate definition>.

From [ITU-T Z.101] clause 12.1.6.2 *Concrete grammar*:

The <structure definition> for a structure *s* represents (in the *Operation-signature* set of the *Data-type-definition* for *s*):

- a) in the absence of data type specialization (see [ITU-T Z.104] clause 12.1.9), if no operator named *Make* is given with an *Operation-result* that is the *Sort-reference-identifier* of the *s* structure sort (an *s* structure result), an *Operation-signature* for a generic operator named *Make* with:
  - i. a *Formal-argument* list where each item is the *Sort-reference-identifier* of the corresponding (in order) <field name> if the referenced <field> does not contain **optional** and does not contain a <field default initialization>;
  - ii. an *Operation-result* that is the *s* structure result;
  - iii. the procedure identified by the *Operation-signature* having each formal parameter of its *Parameter-aggregation* derived from the <aggregation kind> of the corresponding <field name>, and a *Result-aggregation* that is **PART**.

From [ITU-T Z.104] clause 12.1.6.2 *Concrete grammar* and *Semantics*:

- b) if *s* has a <data type specialization> and no *Operation-signature* for an operator named *Make* is given with an *Operation-result* that is the *Sort-reference-identifier* of the *s* structure sort (an *s* structure result), represents (in the *Operation-signature* set of the *Data-type-definition* for *s*) an *Operation-signature* for a generic operator named *Make* for each inherited *Operation-signature* for an operator named *Make* with:
  - i. a *Formal-argument* list that begins with *Sort-reference-identifier* items of the *Formal-argument* list of the inherited *Make* operator and where each subsequent item is the *Sort-reference-identifier* of the corresponding (in order) <field name> if the referenced <field> does not contain **optional** and does not contain a <field default initialization>;
  - ii. an *Operation-result* that is the *s* structure result;
  - iii. the procedure identified by the *Operation-signature* having each formal parameter of its *Parameter-aggregation* derived from the <aggregation kind> of the corresponding <field name>, and a *Result-aggregation* that is **PART**.

The remaining paragraphs of this clause are from [ITU-T Z.101] clause 12.1.6.2 *Concrete grammar*:

- c) for each field, if the <field name> is *f<sub>n</sub>* and the <field sort> is *f<sub>s</sub>*, an *Operation-signature* for the <operation signature>
 

```
fnExtract ( S ) -> fs;
```

 for a generic operator where *fnExtract* is a *field-extract-name* formed from the concatenation of the field name and "Extract", and in the procedure identified by the *Operation-signature* *s* is an **in/out** parameter with an empty <aggregation kind>, and the *Result-aggregation* is derived from the <aggregation kind> of the field *f<sub>n</sub>*.
- d) for each field, if the <field name> is *f<sub>n</sub>* and the <field sort> is *f<sub>s</sub>*, an *Operation-signature* for the <operation signature>
 

```
fnModify ( S, fs ) -> S;
```

 for a generic operator where

$fnModify$  is a *field-modify-name* formed from the concatenation of the field name and "Modify",  
 and in the procedure identified by the *Operation-signature*  
 $S$  is an **in/out** parameter with **PART** *Parameter-aggregation*,  
 $fs$  is an **in** parameter with *Parameter-aggregation* derived from the <aggregation kind> of the field  $fn$ ,  
 and the *Result-aggregation* is **PART**.

- e) for each field, if the <field name> is  $fn$ , an *Operation-signature* for the <operation signature>  
 $fnPresent ( S ) \rightarrow \ll\text{package Predefined}\gg\text{Boolean};$   
 for a generic operator where  
 $fnPresent$  is a *field-present-name* formed from the concatenation of the field name and "Present",  
 and in the procedure identified by the *Operation-signature*  
 $S$  is an **in/out** parameter with **PART** *Parameter-aggregation*  
 and the *Result-aggregation* is **PART**.
- f) an *Operation-signature* for a generic operator named `Undefined` based on the <operation signature>  
 $Undefined ( S ) \rightarrow \ll\text{package Predefined}\gg\text{Boolean};$   
 which is `true` if the structure is "undefined": that is, every field of the structure is "undefined",  
 and in the procedure identified by the *Operation-signature*  
 $S$  is an **in/out** parameter with **PART** *Parameter-aggregation*,  
 and the *Result-aggregation* is **PART**.

From [ITU-T Z.101] clause 12.1.6.3 *Concrete grammar*:

The <choice definition> for a choice sort  $C$  represents (in the *Operation-signature* set of the *Data-type-definition* for  $C$ ):

- a) an *Operation-signature* for a generic operator named `Make` with an empty *Formal-argument* list and an *Operation-result* that is the *Sort-reference-identifier* of the  $C$  choice sort, and the procedure identified by the *Operation-signature* has a *Result-aggregation* that is **PART**.
- b) for each field, if the <field name> is  $fn$  and the <field sort> is  $fs$ , an *Operation-signature* for the operation signature  
 $fn ( fs ) \rightarrow C;$   
 for a generic field association operator where  
 $fn$  is a *field-associate-name* which is the same as the field name,  
 and in the procedure identified by the *Operation-signature*  
 $fs$  is an **in** parameter with *Parameter-aggregation* derived from the <aggregation kind> of field  $fn$ ,  
 and *Result-aggregation* is **PART**.
- c) for each field, if the <field name> is  $fn$  and the <field sort> is  $fs$ , an *Operation-signature* for the <operation signature>  
 $fnExtract ( C ) \rightarrow fs;$   
 for a generic operator where  
 $fnExtract$  is a *field-extract-name* formed from the concatenation of the field name and "Extract",  
 and in the procedure identified by the *Operation-signature*  
 $C$  is an **in/out** parameter with **PART** *Parameter-aggregation*,  
 and *Result-aggregation* is derived from the <aggregation kind> of field  $fn$ .
- d) for each field, if the <field name> is  $fn$  and the <field sort> is  $fs$ , an *Operation-signature* for the <operation signature>  
 $fnModify ( C, fs ) \rightarrow C;$

for a generic operator where

`fnModify` is a *field-modify-name* formed from the concatenation of the field name and "Modify",

and in the procedure identified by the *Operation-signature*

`C` is an **in/out** parameter with **PART** *Parameter-aggregation*,

`fs` is an **in** parameter with *Parameter-aggregation* derived from the <aggregation kind> of field `fn`,

and *Result-aggregation* is **PART**.

- e) for each field, if the <field name> is `fn`, an *Operation-signature* for the <operation signature>

```
fnPresent ( C ) -> <<package Predefined>>Boolean;
```

for a generic operator where

`fnPresent` is a *field-present-name* formed from the concatenation of the field name and "Present",

and in the procedure identified by the *Operation-signature*

`C` is an **in/out** parameter with **PART** *Parameter-aggregation*,

and *Result-aggregation* is **PART**.

- f) an *Operation-signature* for a generic operator named `PresentExtract` based on the <operation signature>

```
PresentExtract ( C ) -> AnonPresent;
```

where `AnonPresent` is defined as a literal constructor data type that uses the field names of the choice as literals as described below,

and in the procedure identified by the *Operation-signature*

`C` is an **in/out** parameter with **PART** *Parameter-aggregation*,

and *Result-aggregation* is **PART**.

- g) an *Operation-signature* for a generic operator named `Undefined` based on the <operation signature>

```
Undefined ( C ) -> <<package Predefined>>Boolean;
```

which is `true` if the choice is "undefined",

and in the procedure identified by the *Operation-signature*

where `C` is an **in/out** parameter with **PART** *Parameter-aggregation*,

and *Result-aggregation* is **PART**.

The <choice definition> for a choice sort `C` also represents an additional (anonymous) *Data-type-definition*, that for description above is called `AnonPresent`. This *Data-type-definition* is placed in the *Data-type-definition* for `C`, therefore both `AnonPresent` and its contained *Literal-signature-set* are visible where `C` is visible. This is defined with a *Literal-signature-set* where each <field name> of the choice sort `C` represents a *Literal-signature*. The order of the literals is the same as the order in which the <field name>s are specified left to right in the choice sort `C`. The purpose of this data type is to allow the operation `PresentExtract` with a result that corresponds to the field name. The name of this data type being unknown prevents it being used for other purposes.

### Auxiliary functions

The function *localDataTypeDefinitionSet0* gets the local defined <data type definition>s in a scope unit.

```
localDataTypeDefinitionSet0(su: SCOPEUNIT0): <data type definition>-set =def  
{d∈<data type definition>: d.surroundingScopeUnit0 = su}
```

The function *structMakeSig0* delivers a single-item sequence containing the <operation signature> for the Make operation implied by a structure definition.

```
structMakeSig0(d :<data type definition>):<operation signature>* =def
```

```

let sort = mk-<sort>( mk-<type expression>( d.identifier0, empty)) in
let struct = d.s-<data type definition body>. s-<structure definition> in
< mk-<operation signature>( // Make with no parameters – first operation signature in list
  mk-<operation preamble>( virtual, undefined), // preamble
  mk-<name>("Make"),
  empty, //arguments list
  mk-<result>( sort)
), // operation signature - Make with no parameters
mk-<operation signature>( // Make with no parameters – second operation signature in list
  mk-<operation preamble>( virtual, undefined), // preamble
  mk-<name>("Make"),
  < mk-<argument>( in, struct.fieldSortList0[n] ) : n in 1..struct.fieldNameList0.length ∧
    expandfieldsSt0(fields)[n] ∈ <mandatory field> ∧
    expandfieldsSt0(fields)[n]. s-<field default initialization> = undefined
  >, //arguments list
  mk-<result>( sort)
) // operation signature
> // list of signatures with 2 elements – signature for Make without/with parameters
endlet // struct
endlet // sort

```

The function *structMakeDef0* delivers the single-item sequence containing the <operation definition> for the Make operation implied by a structure definition.

```

structMakeDef0( d : <data type definition> ): <operation definition>* =def
let sort = mk-<sort>( mk-<type expression>( d.identifier0, empty)) in
let struct = d.s-<data type definition body>. s-<structure definition> in
< mk-<operation definition> ( // Make with no parameters – first operation definition in list
  mk-<operation heading>( operator,
    mk-<operation preamble> ( virtual, undefined), // preamble
    undefined, // qualifier
    mk-<name>("Make"),
    empty, // formal operation parameters = list of formal variable parameters
    mk-<result>( sort)
  ), //operation heading
  empty, // entity list in operator
  mk-<statements>( undefined, // connector name, followed by terminating (dummy return) statement
    mk-<return statement>( mk-<return body>( undefined)) // replaced by actual body in F3
  ) // statements
), // operation definition – Make with no parameters
mk-<operation definition> ( // Make with parameters – second operation definition in list
  mk-<operation heading>( operator,
    mk-<operation preamble> ( virtual, undefined), //preamble, qualifier
    undefined, // qualifier
    mk-<name>("Make"),
    < mk-<formal variable parameters>( in,
      fok.s-<aggregation kind>,
      mk-<parameters of sort>( fok.s-<name>, fok.s-<sort>)
    ) // formal variable parameters
    : fok in
    < struct.s-<field>-seq[i]. s-<mandatory field>. s-<fields of sort>. s-<field of kind>-seq[1]
    : i in 1..struct.s-<field>-seq.length ∧
      struct.s-<field>-seq[i] ∈ <mandatory field> ∧
      struct.s-<field>-seq[i]. s-<mandatory field>. s-<field default initialization> = undefined
    > // list of mandatory fields not initialized
  >, // formal operation parameters = list of formal variable parameters
  mk-<result>( sort)
), //operation heading
  empty, // entity list in operator
  mk-<statements>( undefined, // connector name, followed by terminating (dummy return) statement
    mk-<return statement>( mk-<return body>( undefined)) // replaced by actual body in F3
  ) // statements
), // operation definition – Make with parameters

```

```

> // list of Make definitions without/with parameters
endlet // struct
endlet // sort

```

The function *structOpSigs0* delivers a list of <operation signature>s for operations to: extract the value of a specified field, to modify the value of a specified field, test if a field is present, and check if all fields of a choice are undefined. That is:

for each field with name *fn* where *fs* is the field sort

the operator *fnExtract*(*S*) -> *fs*; extract the value of field *fn*

the operator *fnModify*(*S*, *fs*) -> *S*; modify field *fn* of the structure,

the operator *fnPresent*(*S*) -> Boolean; test if the field *fn* is present

plus for the Structure data type as a whole

the operator *Undefined*(*S*) -> Boolean; check if choice undefined.

```

structOpSigs0(d :<data type definition>):<operation signature>* =def
let struct = d.s-<data type definition body>.s-<structure definition> in
< mk-<operation signature>(
  mk-<name>(s.fieldNameList0[n].s-TOKEN + "Modify"),
  < mk-<argument>(inout, d.identifier0) > ^
    < mk-<argument>(in, s.fieldSortList0[n]) >,
  mk-<result>(sort) | n in 1..s.fieldNameList0.length > ^
< mk-<operation signature>(
  mk-<name>(s.fieldNameList0[n].s-TOKEN + "Extract"),
  < mk-<argument>(inout, d.identifier0) >,
  mk-<result>(s.fieldSortList0[n],empty) | n in 1..s.fieldNameList0.length > ^
< mk-<operation signature>(
  mk-<name>(s.fieldNameList0[n].s-TOKEN + "Present"),
  < mk-<argument>(inout, d.identifier0) >,
  mk-<result>(predefinedId0("Boolean"))
  | n in 1..s.fieldNameList0.length ^ fields[n] ∈ <optional field> > ^
< mk-<operation signature> (
  mk-<operation preamble> (undefined, undefined),
  mk-<name>("Undefined"),
  mk-<arguments>( <
    mk-<formal parameter>(inout, mk-<sort>(mk-<type expression>(d.identifier0,empty)))
  >), // arguments
  mk-<result>(mk-<sort>(mk-<type expression>(predefinedId0("Boolean"),empty)))
> // Undefined signature
endlet

```

The function *structOpDefs0* delivers a list of <operation definition>s for structure operations to modify and access the fields of a Structure data type.

```

structOpDefs0(d :<data type definition>):<operation definition>* =def
let struct = d.s-<data type definition body>.s-<structure definition> in
let sort = mk-<sort>(mk-<type expression>(d.identifier0,empty)) in
let allFields = struct.s-<field list>.s-<optional field>.s-<fields of sort> ^
  struct.s-<field list>.s-<mandatory field>.s-<fields of sort> in
< mk-<operation definition> (empty, // package use
  mk-<operation heading> (operator,
    mk-<operation preamble> (virtual, undefined), //preamble
    empty, // qualifier
    mk-<name>(f.s-<field of kind>-seq[1].s-<name>.s-TOKEN + "Modify"),
    < mk-<formal variable parameters>(inout,
      part,
      <parameters of sort>( < mk-<name>("structValue") >, sort) // parameters of sort
    ), // formal variable parameters – first parameter - struct
    mk-<formal variable parameters>(in,
      f.s-<field of kind>-seq[1].s-<aggregation kind>,
      <parameters of sort>( < mk-<name>("fieldValue") >, f.s-<sort>)
    ) // formal variable parameters – second parameter - field
  )

```

```

    >, // formal operation parameters = list of formal variable parameters
    mk-<operation result> (<part, undefined, sort) // result - struct
  ) // operation heading
  empty, // entity list in operator

```

The function *anonLiterals0* delivers an anonymous <data type definition> with a <literal list> containing all the <field name>s from the <choice of sort>s in a Choice data type as <literal name>s.

```

anonLiterals0(cdef: <choice definition>, nn: <name>):<data type definition> =def
mk-<data type definition>(empty, undefined,
    mk-<data type heading>(mk-<name>(nn.s-TOKEN + "Present"), empty, undefined), undefined,
    mk-<data type definition body>(empty,
        mk-<literal list>(undefined, // visibility
            <c.s-<name> : c in ( cdef.s-<choice list> ) > // list of literal names
        ), // literal list
        mk-<operations>( <operation signatures>( <operator list>(empty), <method list>(empty)), empty),
        undefined // initialization
    ) // data type definition body
) // data type definition
endlet

```

The function *choiceOpSigs0* delivers an <operation signature> list for operations to: make an undefined choice value, create a choice value with the specified field with the given value, *to modify and access* the fields of a choice, test if a field is present, find which field is present in a choice, and check if all fields of a choice are undefined. That is,  
the operator `Make () -> C`; to make an undefined value,  
plus for each field `fn`  
the operator `fn(fs) -> C`; create a choice value,  
the operator `fnModify(C, fs) -> C`; modify a choice,  
the operator `fnExtract(C) -> fs`; extract the current choice value and  
the operator `fnPresent(C) -> Boolean`; test if the field is present  
plus for the Choice data type as a whole  
the operator `PresentExtract(C) -> AnonPresent`; name of the present field and  
the operator `Undefined(C) -> Boolean`; check if choice undefined.

```

  >), // arguments
  mk-<result>(mk-<sort>(mk-<type expression>(predefinedId0("Boolean"),empty)))
> // Undefined signature

```

The function *choiceOpDefs0* delivers an <operation definition> list for choice operations as listed in the description of *choiceOpSigs0*. The body of each operation is here given as a dummy return, which is copied to the implicit procedure for the operation and replaced in the dynamic semantics in F3 by the action needed.

*choiceOpDefs0*(d :<data type definition>, nn: <name>):<operation definition>\* =<sub>def</sub>

```

< mk-<operation definition> (

> // Undefined operation definition

```

Given a <data type definition>, the function *getOpSigs0* delivers a list of <operation signature>s. The list is formed by concatenating the <operator list> from the <data type definition> with modified <operation signature>s from the <method list> of the <data type definition>. The modification entails adding the identifier of the parent <data type definition> as an additional argument to each <operation signature> in the <method list> (see clause F2.2.9.5).

```

getOpSigs0(d :<data type definition>):<operation signature>* =def
let ops = d.s-<data type definition body>.s-<operations>.s-<operation signatures>.s-<operator list> in
let meths = d.s-<data type definition body>.s-<operations>.s-<operation signatures>.s-<method list> in
ops ^
< mk-<operation signature>(
  m.s-<operation preamble>,
  m.s-<operation name>,
  mk-<arguments>(
    < mk-<argument>(inout, mk-<sort>(mk-<type expression>(d.identifier0,empty))) > ^
    if m.s-<arguments> = undefined then empty else m.s-<arguments> endif,
  ) // arguments
  if m.s-<result> = undefined
  then mk-<sort>(mk-<type expression>(d.identifier0,empty))
  else m.s-<result>
  endif
) // operation signature
: m in meths >
endlet // meths
endlet // ops

```

### F2.2.9.3 Interface type

#### Abstract syntax

<i>Interface-definition</i>	::	<i>Sort</i> <i>Null-literal-signature</i> <i>Data-type-identifier-set</i> <i>Signal-definition-set</i> <i>Signal-identifier-set</i>
<i>Null-literal-signature</i>	=	<i>Literal-signature</i>
<i>Sort</i>	=	<i>Name</i>

#### Concrete syntax

```

<interface definition> ::
  <package use clause>* [<virtuality>] <interface heading> [<interface specialization>]
  <entity in interface>*
  | <signal list definition>
<interface heading> ::

```

$\langle \text{interface} \langle \text{name} \rangle [ \langle \text{formal context parameters} \rangle ] [ \langle \text{virtuality constraint} \rangle ]$   
 $\langle \text{entity in interface} \rangle =$   
 $\quad \langle \text{signal definition list} \rangle$   
 $\quad | \langle \text{interface variable definition} \rangle$   
 $\quad | \langle \text{interface procedure definition} \rangle$   
 $\quad | \langle \text{interface use list} \rangle$   
 $\langle \text{interface use list} \rangle :: [ \langle \text{signal list} \rangle ]$   
 $\langle \text{interface variable definition} \rangle :: \langle \text{remote variable} \langle \text{name} \rangle + \langle \text{sort} \rangle$   
 $\langle \text{interface procedure definition} \rangle :: \langle \text{remote procedure} \langle \text{name} \rangle \langle \text{procedure signature} \rangle$   
 $\langle \text{as interface} \rangle :: \langle \text{interface} \langle \text{identifier} \rangle$

## Conditions on concrete syntax

$\forall ifd \in \langle \text{interface definition} \rangle:$   
 $isRestrictedByInterface0(ifd.s \langle \text{entity in interface} \rangle.s \langle \text{interface use list} \rangle.s \langle \text{signal list item} \rangle.seq)$

Each  $\langle \text{signal list item} \rangle$  of the  $\langle \text{signal list} \rangle$  in an  $\langle \text{interface use list} \rangle$  of an  $\langle \text{interface} \langle \text{definition} \rangle$  shall be a  $\langle \text{signal} \langle \text{identifier} \rangle$  or an  $\langle \text{interface} \langle \text{identifier} \rangle$  or a  $\langle \text{remote procedure} \langle \text{identifier} \rangle$  or a  $\langle \text{remote variable} \langle \text{identifier} \rangle$ . An  $\langle \text{interface} \langle \text{identifier} \rangle$  that is part of the  $\langle \text{signal list} \rangle$  shall also respect the restriction. See clause 12.1.2 *Concrete grammar* of [ITU-T Z.101] and clause 10.4 *Concrete grammar* of [ITU-T Z.102].

$\forall interfaceDef \in \langle \text{interface definition} \rangle: \neg isInterfaceDefContaining0(interfaceDef, interfaceDef)$

The  $\langle \text{interface definition} \rangle$  shall not contain the  $\langle \text{interface} \langle \text{identifier} \rangle$  defined by the  $\langle \text{interface definition} \rangle$  either directly or indirectly (via another  $\langle \text{interface} \langle \text{identifier} \rangle$ ). See clause 12.1.2 *Concrete grammar* of [ITU-T Z.101].

$\forall ind \in \langle \text{interface definition} \rangle: \forall fcp \in \langle \text{formal context parameter} \rangle:$   
 $fcp \in ind.localFormalContextParameterList0 \Rightarrow$   
 $fcp \in \langle \text{signal context parameter list} \rangle \cup \langle \text{remote procedure context parameter} \rangle \cup$   
 $\langle \text{remotevariable context parameter list} \rangle \cup \langle \text{sort context parameter} \rangle$

The  $\langle \text{formal context parameters} \rangle$  shall only contain  $\langle \text{signal context parameter list} \rangle$ ,  $\langle \text{remote procedure context parameter} \rangle$ ,  $\langle \text{remotevariable context parameter list} \rangle$  or  $\langle \text{sort context parameter} \rangle$ .

$ifd.asInterfaceName$   
**provided**  
 $ifd \in \langle \text{interface definition} \rangle$   
 $\wedge ifd.asInterfaceName = undefined$   
 $=8=>$   
 $(asInterfaceName \setminus \{ (ifd, undefined) \}) \cup \{ (ifd, newName) \}$

NOTE 1 – Each  $\langle \text{interface definition} \rangle$  defines a *Data-type-definition* of a choice data type with a unique anonymous *Sort* name stored in *asInterfaceName*.

$\langle \text{as interface} \rangle (ifd)$   
**provided**  
 $ifd.refersto0.asInterfaceName \neq undefined$   
 $=8=>$   
 $mk \langle \text{type expression} \rangle (mk \langle \text{identifier} \rangle (ifd.s \langle \text{qualifier} \rangle, ifd.refersto0.asInterfaceName), undefined)$

An  $\langle \text{as interface} \rangle$  represents the sort of the choice data type introduced by the identified interface definition. See clause 12.1.2 *Concrete grammar* of [ITU-T Z.104].

## Mapping to abstract syntax

$| idf = \langle \text{interface definition} \rangle (*, *, \langle \text{interface heading} \rangle (name, *, *), spec, entities)$  **then**  
 $mk \text{-Interface-definition}(Mapping(name),$   
 $mk \text{-Literal-signature}(mk \text{-Name}("null"),$

```

mk-Result(mk-Identifier(Mapping(idef.fullQualifier0), Mapping(name)),
mk-Result-aggregation(REF),
0), // null literal signature
Mapping(spec), // set of identities of inherited interface definitions
{ e ∈ Mapping(entities).toSet: (e ∈ Signal-definition)}, // signal definitions defined in the interface
{ sigid ∈ idef.usedSignalSet0} ∪ {sd.identifier0 | sd ∈ idef.definedSignalSet0} //ids of sigs def for i/f
)

```

NOTE 2 – The mapping to a *Data-type-definition* for the choice data type defined by a <interface definition> in the following paragraph takes place by invoking the function *choiceForInterface1* (defined below), in the mappings to *Package-definition* in clause F2.2.4.2, *Agent-type-definition* in clauses F2.2.5.1.2, F2.2.5.1.3 and F2.2.5.1.4, *Composite-state-type-definition* in clause F2.2.5.1.5, *Procedure-definition* in clause F2.2.6.4, and *Procedure-definition* in clause F2.2.6.4.

A <basic sort> that is <as interface> where <interface identifier> identifies the *Interface-definition*, represents this *Data-type-definition*. The *Data-type-definition* is equivalent to defining a choice data type with a <choice of sort> for each distinct *Signal-definition* identified by the *Signal-identifier-set* of the *Interface-definition*. The <field name> and <field sort> for each <choice of sort> is determined in the same way as a <choice of sort> for each distinct *Signal-definition* of the *Data-type-definition* defined by a <gate definition>. See clause 12.1.2 *Concrete grammar* of [ITU-T Z.104].

### Auxiliary functions

The function *localInterfaceDefinitionSet0* gets the local defined interface definition list of a scope unit.

```

localInterfaceDefinitionSet0(su: SCOPEUNIT0): <interface definition>-set =def
{d ∈ <interface definition>:d.surroundingScopeUnit0 = su}

```

The function *isRestrictedByInterface0* decides if each <signal list item> of a list is a <signal<identifier>, <remote procedure<identifier>, <remote variable<identifier> or <interface<identifier>. An <interface<identifier> that is part of the list shall also respect the restriction.

```

isRestrictedByInterface0(sl: <signal list item>*): BOOLEAN =def
if sl = empty then true
else
  case sl.head.s-implicit of
    | {signal, remote procedure, remote variable} then isRestrictedByInterface0(sl.tail)
    | {interface} then
      let s1 = getEntityDefinition0(sl.head.s-<identifier>, interface).s-<signal list item>-seq in
        isRestrictedByInterface0(s1) ∧ isRestrictedByInterface0(sl.tail)
      otherwise false
  endcase
endif

```

The function *isInterfaceDefContaining0* is used to determine if the first interface definition contains the second interface definition, either directly or indirectly.

```

isInterfaceDefContaining0(id1: <interface definition>, id2: <interface definition>): BOOLEAN =def
(∃ useList ∈ <interface use list>:
  useList.parentAS0 = id1
  ∧ (∃ ident ∈ <identifier>:
    ident.idKind0 = interface
    ∧ ident = useListItem.s-<signal list item>
    ∧ useListItem in useList
    ∧ (
      getEntityDefinition0(ident, interface) = id2
      ∨ (∃ id3 ∈ <interface definition>:
        isInterfaceDefContaining0 (id1, id3) ∧ isInterfaceDefContaining0 (id3, id2)
        ) // id3
      ) // getEntityDefinition0 ...
  )

```

```

) // ident
) // useList

```

The function *choiceForInterfaceI* produces the choice *Data-type-definition* that corresponds to a *Interface-definition* and is used when an *<as interface>* is given for a *<basic sort>*, where each *<choice of sort>* is for each distinct signal definition identified by the interface definition.

```

choiceForInterfaceI(ifd: <interface definition>): Data-type-definition =def
let ifSigSet =
{ sigid ∈ ifd.usedSignalSet0 } ∪ { sd.identifier0 | sd ∈ ifd.definedSignalSet0 } //ids of sigs def for i/f
in
Mapping(mk-<data type definition>( mk-<type preamble>(undefined, undefined), // type preamble
mk-<data type heading>( ifd.asInterfaceName, // name for choice type
undefined, undefined, // no formal parameters or virtuality constraint
), // data type heading
mk-<data type definition body>( empty, // no entities in data type
mk-<choice definition>( undefined, // visibility
< mk-<choice of sort>(undefined, // visibility
mk-<field of kind>( part,
if sig.s-<name> ∉ { othersigs.s-<name>
: othersigs ∈ (ifSigSet \ sig ) }
then // unique signal name
sig.s-<name>
else // not unique signal name – name same as <as signal>
sig.asSignal.s-<name> // name of structure sort for signal
endif
), // <field of kind>
mk-<field sort>(
if sig.refersTo0.s-implicit // <sort list> | <named fields sort list> | <sort-identifier>
= undefined // no sort
then predefinedId0("NULL")
else sig.asSignal // structure sort for signal
endif
) // <field sort>
) // <choice of sort> item
: sig ∈ ifSigSet
> // <choice of sort> list
) <choice definition>(
), // data type definition body
undefined // default initialization
)) // Mapping of data type definition
endlet // ifSigSet

```

The function *asInterfaceName* associates each *<interface definition>* with a unique anonymous name for the *Sort* of the corresponding *Data-type-definition* of the choice data type invoked by *<as interface>*.

```

controlled asInterfaceName: <interface definition> → <name>
initially ∇ ifd ∈ <interface definition>: ifd.asInterfaceName = undefined

```

## F2.2.9.4 Specialization of data types

### Concrete syntax

```

<data type specialization> :: <data type><type expression> <renaming>
<renaming> :: <rename list>
<rename list> = <rename pair>*
<rename pair> =
<rename pair operation name> | <rename pair literal name>
<rename pair operation name> :: <operation name> <base type><operation name>

```

<rename pair literal name> :: <literal name> <base type><literal name>

<interface specialization> :: <interface><type expression>+

## Conditions on concrete syntax

See clause 12.1.9 *Concrete grammar* of [ITU-T Z.104].

$\forall sp \in \langle \text{data type specialization} \rangle: \forall te \in sp.s \langle \text{type expression} \rangle:$

$\neg isAbstractType0(te.BaseType0) \Rightarrow \forall te' \in sp.s \langle \text{type expression} \rangle \setminus \{te\}: isAbstractType0(te'.BaseType0)$

At most one of the <data type><type expression>s is allowed to be not abstract.

$\forall dataDef \in \langle \text{data type definition} \rangle: \forall superTypeDef \in \langle \text{data type definition} \rangle:$

$isSubtype0(dataDef, superTypeDef) \Rightarrow$

$superTypeDef.s \langle \text{data type definition body} \rangle.s \langle \text{data type constructor} \rangle = undefined \vee$

$isSameConstructorKind0($

$superTypeDef.s \langle \text{data type definition body} \rangle.s \langle \text{data type constructor} \rangle,$

$dataDef.s \langle \text{data type definition body} \rangle.s \langle \text{data type constructor} \rangle)$

The <data type constructor> with the <data type specialization> shall be of the same kind as the <data type constructor> used in the <data type definition> of the sort referenced by <data type><type expression> in the <data type specialization>: if the <data type constructor> used in a (direct or indirect) supertype was a <literal list>, the <data type constructor> shall be a <literal list>; if the supertype <data type constructor> was a <structure definition>, the subtype <data type constructor> shall be a <structure definition>.

$\forall rn \in \langle \text{renaming} \rangle:$

**let**  $lnl = \langle \langle rp.s \langle \text{literal name} \rangle, rp.s2 \langle \text{literal name} \rangle \rangle \mid rp \text{ in } rn.s \langle \text{rename pair} \rangle \text{-seq} \rangle$  **in**

**let**  $onl = \langle \langle rp.s \langle \text{operation name} \rangle, rp.s2 \langle \text{operation name} \rangle \rangle \mid rp \text{ in } rn.s \langle \text{rename pair} \rangle \text{-seq} \rangle$  **in**

$(\forall i, j \in 1..lnl.length: i \neq j \Rightarrow lnl[i] \neq lnl[j]) \wedge$

$(\forall i, j \in 1..onl.length: i \neq j \Rightarrow onl[i] \neq onl[j])$

All <literal name>s and all <base type><literal name>s in a <rename list> shall be distinct. All <operation name>s and all <base type><operation name>s in a <rename list> shall be distinct.

$\forall sp \in \langle \text{data type specialization} \rangle:$

**(let**  $bt = sp.s \langle \text{type expression} \rangle.BaseType0$  **in**

**let**  $onl = \langle rp.s2 \langle \text{operation name} \rangle \mid$

$rp \text{ in } sp.s \langle \text{renaming} \rangle.s \langle \text{rename pair} \rangle \text{-seq}: rp \in \langle \text{rename pair operation name} \rangle \rangle$  **in**

$\forall on \in \langle \text{operation name} \rangle: on \text{ in } onl \Rightarrow$

$(\exists os \in \langle \text{operation signature} \rangle: os.surroundingScopeUnit0 = bt \wedge on = os.name0)$

**endlet)**

A <base type operation name> specified in a <rename list> shall be an operation with <operation name> defined in the data type definition defining the <base type> of <data type><type expression>.

## Transformations

The model for specialization in clause 8.4 of [ITU-T Z.102] is used, augmented by clause 12.1.9 *Model of* [ITU-T Z.104] for data type specialization.

<data type definition>(use, preamble, heading, spec, undefined) // no data type definition body  
=11=>

**mk**-<data type definition>(use, preamble, heading, spec,

**mk**-<data type definition body>(undefined, // entities

undefined, // data type constructor

inheritedOperations0(spec), // operations

undefined)) // default initialization

<data type definition>

( use, preamble, heading, spec, dtdb=<data type definition body>

(entities, constr, <operations>

```

    (<operation signatures> (<operator list>(ops), <method list> (meths)), opDefsAndRefs, init) )
provided dtdb ≠ undefined // separate transformation
=11=>
mk-<data type definition>(use, preamble, heading, spec,
    mk-<data type definition body>( entities, constr,
        mk-<operations>(<operation signatures>(
            if dtdb.s-<operation signatures>.s-<operator list> ≠ undefined
            then <operator list>(ops)
            else empty
            endif ^
                inheritedOperations0(spec).s-<operation signatures>.s-<operator list>,
            if dtdb.s-<operation signatures>.s-<method list> ≠ undefined
            then <method list> (meths)
            else empty
            endif ^
                inheritedOperations0(spec).s-<operation signatures>.s-<method list>),
            opDefsAndRefs ^ inheritedOperations0(spec).s-<operation definitions>), init))

```

The following paragraphs are from clause 12.1.9 *Model of* [ITU-T Z.104].

A specialized data type is based on another (base) data type by using a <data type definition> in combination with a <data type specialization>. The sort defined by the specialization is disjoint from the sort defined by the base type.

If the sort defined by the base type has literals defined, the literal names are inherited as names for literals of the sort defined by the specialized type unless literal renaming has taken place for that literal. Literal renaming has taken place for a literal if the base type literal name appears as the second name in a <rename pair> in which case the literal is renamed to the first name in that pair.

If the base type has operators or methods defined, the operation names are inherited as names for operators or methods of the sort being defined, unless the operator or method has been declared as private (see clause 12.1.8.4 of [ITU-T Z.104]) or operation renaming has taken place for that operator or method. Operation renaming has taken place for an operator or method if the inherited operation name appears as the second name in a <rename pair> in which case the operator or method is renamed to the first name in that pair.

When several operators or methods of the <base type> of <sort type expression> have the same name as the <base type operation name> in a <rename pair>, then all of these operators or methods are renamed.

In the following paragraphs ST is a subsort that is a specialization of a data type T, and Tid is an <identifier> for data type T.

For every occurrence of a <basic sort> of the form Tid in a specialization of T, the <basic sort> is replaced by the <basic sort> of the subsort: that is, the <identifier> for the subsort ST. Every occurrence of an <anchored sort> of the form **parent** T in a specialization of T, the <anchored sort> is replaced by an unambiguous qualified <basic sort> for the base type T: that is, the qualified <identifier> for T. Every occurrence of an <anchored sort> of the form **this** T in a specialization of T, the <anchored sort> is replaced by the <basic sort> of the subsort: that is, the <identifier> for the subsort ST.

The argument sorts and result of an inherited operator or method are the same as those of the corresponding operator or method of the base type, except that every <argument> in T that is a <basic sort> T or an <anchored sort> of the form **this** T, in the inherited operator or method the <anchored sort> is replaced by the subsort ST.

NOTE – Anchored sorts are handled in the functions *inheritedOperations0* and *doRename*.

### Mapping to abstract syntax

```
| <data type specialization>(base, *) then Mapping(base)
```

```
| <interface specialization>(bases, *) then
  { Mapping(bases[i]) | i ∈ 1..bases.length } // set of inherited interface identifiers
```

## Auxiliary functions

The function *isRenamedBySpec0* determines if a <literal signature> or an <operation signature> is renamed by a <data type specialization>.

```
isRenamedBySpec0(sn:<literal signature>∪<operation signature>, spec:<data type specialization>):
  BOOLEAN =def
  (∃rp ∈ <rename pair>:
    (rp.parentAS0.parentAS0 = spec) ∧
    (rp.s2-<literal name> = sn.name0 ∨ rp.s2-<operation name> = sn.name0))
```

The function *isSameConstructorKind0* is used to determine if two data type constructor items are of the same kind.

```
isSameConstructorKind0(c1:<data type constructor>, c2:<data type constructor>): BOOLEAN =def
  (c1 ∈ <literal list> ∧ c2 ∈ <literal list>) ∨
  (c1 ∈ <structure definition> ∧ c2 ∈ <structure definition>) ∨
  (c1 ∈ <choice definition> ∧ c2 ∈ <choice definition>)
```

Sort compatibility determines when a sort can be used in place of another sort, and when it cannot. The function *isSortCompatible0* is used to determine if the first sort is sort compatible to the second one.

```
isSortCompatible0(sort1:<sort>, sort2:<sort>): BOOLEAN =def
  isSameSort0(sort1, sort2) ∨
  isDirectlySortCompatible0(sort1, sort2) ∨
  (isPidSort0(sort2) ∧
    ∃sort3 ∈ <sort>: isSortCompatible0(sort1, sort3) ∧ isSortCompatible0(sort3, sort2))
```

The function *isSameSort0* is used to determine if the given two sorts are the same. As well as being the same if they are equal, they are treated as if they are the same if they have the same derived data type (as long as this is not *undefined*); or they both anchored sorts and *sortId0* is equal; or if they are both for the same interface definition.

```
isSameSort0(sort1: <sort>, sort2: <sort>): BOOLEAN =def
  ( sort1 = sort2 ) // simple case
  ∨
  ( getEntityDefinition0(sort1.sortId0, sort).derivedDataType0 =
    getEntityDefinition0(sort2.sortId0, sort).derivedDataType0
    ∧ getEntityDefinition0(sort1.sortId0, sort).derivedDataType0 ≠ undefined
  ) // same sort when syntypes changed to sort derived from
  ∨
  ( sort1.s-<anchored sort> ≠ undefined ∧ sort2.s-<anchored sort> ≠ undefined ∧
    sort1.sortId0 = sort2.sortId0
  ) // both anchored sorts that expand to the same sort id
  ∨
  ( let def1 = getEntityDefinition0(sort1.sortId0, interface) in
    def1 ∈ <interface definition> ∧ def1 = getEntityDefinition0(sort2.sortId0, interface)
    endlet // def1
  )
```

Determine if two sort lists are the same.

```
isSameSortList0(sl, sl1: <sort>*): BOOLEAN =def
  (sl.length = sl1.length) ∧
  (∀i ∈ 1..sl.length: isSameSort0(sl[i], sl1[i]))
```

The function *isDirectlySortCompatible0* is used to determine if the sort in the first argument is directly sort compatible to the one in the second.

```
isDirectlySortCompatible0(sort1:<sort>, sort2:<sort>): BOOLEAN =def
(sort1 ∈ <anchored sort> ∧ sort1.s-<basic sort> = sort2) ∨
(sort1 ∈ <pid sort> ∧ isSubSort0(sort1, sort2))
```

The function *isPidSort0* is used to determine if a sort is a pid sort.

```
isPidSort0(sort: <sort>): BOOLEAN =def
  getEntityDefinition0(sort.sortId0, interface) ∈ <interface definition>
  ∨ sort.sortId0 = predefinedId0("Pid")
```

The function *isSubSort0* is used to determine if the sort given in the first argument is a super sort of the one in the second.

```
isSubSort0(sort1: <sort>, sort2: <sort>): BOOLEAN =def
let td1 = getEntityDefinition0(sort1.sortId0, sort) in
let td2 = getEntityDefinition0(sort2.sortId0, sort) in
  (td1 ∈ <interface definition> ⇒ isSubtype0(td1, td2)) ∧
  (td1 ∈ <data type definition> ∪ <syntype definition> ⇒
    isSubtype0(td1.derivedDataType0, td2.derivedDataType0))
endlet
endlet
```

The function *inheritedOperations0* computes the operations inherited from the base type.

```
inheritedOperations0(spec: <data type specialization>): <operations> =def
let ops = { o ∈ <operation signature>: isVisibleThroughBaseType0(o, spec.parentAS0)
  ∧ o.parentAS0 ∈ <operator list>} in
let meths = { o ∈ <operation signature>: isVisibleThroughBaseType0(o, spec.parentAS0)
  ∧ o.parentAS0 ∈ <method list>} in
mk-<operations>(
  mk-<operation signatures>(
    if ops ≠ undefined then mk-<operator list>(doRename(ops, spec)) endif, // sigs of operators
    if meths ≠ undefined then mk-<method list>(doRename(meths, spec)) endif // sigs methods
  ),
  undefined // Further study needed here to include operation definitions
  // copied from base type, with name replaced if renamed,
  // parameters/result updated and body updated (inherited sort changed).
)
endlet // meths
endlet // ops
```

The function *doRename* takes a set of operation signatures (in a data type definition) and produces a revised list of the operation signatures where the names are updated according to the renaming given in a data type specialization (of a data type definition) and arguments and results updated in the signatures to take account of anchored sorts and to use the subsort to replace the sort in the data type specialization.

```
doRename(sigssset: <operation signature>-set, spec: <data type specialization>): <operation signature>* =def
let sig ∈ sigssset in
< mk-<operation signature>( sig.s-<operation preamble>,
  if isRenamedBySpec0(sig, spec) then
    take({ n ∈ <name>: n = renamepair.s1-<name> ∧ renamepair in spec.s-<renaming>})
  else sig.s-<name>
  endif,
  < reviseArgResSort0(a, spec): a in sig.s-<arguments> >,
  reviseArgResSort0(sig.s-<result>, spec)
>
)
```

```

if | sigsset | = 1 then empty
else doRename(sigsset \ { sig }, spec )
endif
endlet // sig

```

The function *reviseArgResSort0* takes an argument or result and updates the sort if necessary according to the given data type specialization. The function can also handle a sort parameter, but this is only for the function to call itself recursively. When called with an argument (or result or sort), an argument (or result or sort respectively) is returned. For sort that is an anchored sort with **this**, the function returns the subsort to the recursive call (except if the subsort is not a specialization of the basic sort given with the anchored sort in which case the basic sort is returned). For sort that is an anchored sort with **parent**, the function returns to the recursive call: the sort in the data type specialization to the recursive call if no basic sort is given; anchored sort unchanged if the subsort is not a specialization of the basic sort given with the anchored sort; otherwise the basic sort given. For a sort that is not an anchored sort, the function returns to the recursive call the sort any occurrence of the identifier of the sort in the data type specialization changed to the identifier of the subsort.

```

reviseArgResSort0(arg: <argument> ∪ <result> ∪ <sort>, spec: <data type specialization>):
  <argument> ∪ <result> ∪ <sort> =def
  let subsortId = spec.parentAS0.identifier0 in
  let subsort = mk-<sort>(
    mk-<type expression>(getEntityDefinition0(subsortId, sort).derivedDataType0,empty),undefined) in
  let supersortId = spec.s-<type expression>.s-<identifier> in
  let supersort =
    mk-<sort>(mk-<type expression>(getEntityDefinition0(supersortId, sort),empty),undefined) in
  case arg of
  | <argument>( kind, sort) then
    mk-<argument>( kind, reviseArgResSort0(sort, spec))
  | <result>(sort) then mk-<result>( reviseArgResSort0(sort, spec))
  | <anchored sort> (this) then subsort
  | <anchored sort> (this, basicsort) then
    if isSubSort0(basicSort.sortId0, subsortId) then subsort else basicsort endif
  | <anchored sort> (parent) then supersort
  | <anchored sort> (parent, basicsort) then
    if isSubSort0(basicSort.sortId0, subsortId) then arg else basicsort endif // remains anchored if subsort
  otherwise
    replaceInSyntaxTree0(supersortId, subsortId, arg) // change sort to subsort
  endcase
  endlet // supersort
  endlet // supersortId
  endlet // subsort
  endlet // subsortId

```

## F2.2.9.5 Operations

### Abstract syntax

<i>Static-operation-signature</i>	::	<i>Operation-signature</i>
<i>Dynamic-operation-signature</i>	::	<i>Operation-signature</i>
<i>Operation-signature</i>	::	<i>Operation-name Formal-argument*</i> [ <i>Operation-result</i> ] <i>Procedure-identifier</i>
<i>Formal-argument</i>	=	<i>Argument</i>
<i>Operation-result</i>	=	<i>Sort-reference-identifier</i>
<i>Argument</i>	=	<i>Sort-reference-identifier</i>

### Conditions on abstract syntax

### Concrete syntax

```

<operation signatures> :: [ <operator list> ] [ <method list> ]

```

```

<operator list> :: <operation signature>+
<method list> :: <operation signature>+
<operation signature> :: <operation preamble> <operation name> [<arguments>] [ <result> ]
<operation preamble> :: [<visibility> [<virtuality>]] | [<virtuality> [<visibility>]]
<arguments> :: <argument> +
<argument> = <formal parameter>
<formal parameter> :: <parameter kind> <sort>
<result> :: <sort>

```

## Transformations

```

osigs = <operation signatures>((
  <operator list>(operations),
  <method list> (<operation signature>(pre, name, args, result) ^ rest))
=2=>
mk-<operation signatures>( mk-<operator list>(operations ^
  mk-<operation signature>(pre, name,
  mk-<argument>(inout, parentAS0ofKind(osigs, <data type definition>).identifier0) ^
    if args = undefined then empty else args endif,
  if result ≠ undefined then result
  else parentAS0ofKind(osigs, <data type definition>).identifier0
  endif )),
  mk-<method list>(rest))

```

If <operation signature> is contained in a <method list> this is derived syntax and is transformed as follows: An <argument> is constructed from the <parameter kind> **in/out**, and the <sort identifier> of the sort being defined by the enclosing <data type definition>. If there are no <arguments> (that is the argument list was empty), then <arguments> is formed from the constructed <argument> and inserted into the <operation signature>. If there are <arguments>, the constructed <argument> is added to the start of the original list of <argument>s in the <arguments>. If the <result> was omitted, the <result> is the <sort identifier> of the sort being defined by the enclosing <data type definition>. See clause 12.1.3 *Model* of [ITU-T Z.104].

```

<formal parameter>(undefined, sort) =2=> mk-<formal parameter>(in, sort)

```

A <formal parameter> with no explicit <parameter kind> has the implicit <parameter kind> **in**. See clause 9.4 *Model* of [ITU-T Z.103].

## Mapping to abstract syntax

```

| <operation signatures>(operators, *)
then
  { Mapping(operators[i] | i ∈ 1.. operators.length }

| os = <operation signature>( pre, name, arguments, result) then
let opsig = mk-Operation-signature(
  uniqueOperationName0(name,
    < arguments[i].s-<formal parameter>.s-<sort> | i ∈ 1..arguments.length >
    result.s-<sort>,
    mk-<sort>(mk-<type expression>(parentAS0ofKind(os, <data type definition>).identifier0, empty))),
  Mapping(arguments),
  Mapping(result),
  Mapping(os.operatorProcedureId)) in
if pre.s-<virtuality> = virtual ∨ pre.s-<virtuality> = redefined
then
  mk-Dynamic-operation-signature(opsig)
else

```

```

    mk-Static-operation-signature(opsig)
  endif
endlet // opsig

```

The following three text paragraphs are from clause 12.1.3 *Concrete grammar* of [ITU-T Z.101].

An <operation signature> of an <operator list> represents a *Static-operation-signature*.

In an *Operation-signature*, each *Sort-reference-identifier* in *Formal-argument* is represented by an argument <sort>, and the *Operation-result* is represented by the result <sort>. The <sort> in the <formal parameter> of an <argument> of an operation represents the *Formal-argument*.

The *Operation-name* is unique within the defining scope unit in the abstract syntax even though the corresponding <operation name> is not necessarily unique. The unique *Operation-name* is derived from:

- a) the <operation name>; plus
- b) the (possible empty) list of argument sort identifiers; plus
- c) the result sort identifier; plus
- d) the sort identifier of the data type definition in which the <operation name> is defined.

An <operation signature> with <virtuality> **virtual** or **redefined** in the <operation preamble> represents a *Dynamic-operation-signature*. See clause 12.1.3 *Concrete grammar* of [ITU-T Z.107].

### Auxiliary functions

The function *operatorProcedureId* associates each operation signature with its implicit anonymous procedure identifier.

```

controlled operatorProcedureId: <operation signature> → <identifier>
initially ∇ o ∈ <operation signature>: o.operatorProcedureId = undefined

```

The function *operationSignatureParameterList0* gets the list of the arguments of an operation signature.

```

operationSignatureParameterList0(os: <operation signature>):<formal parameter>* =def
  (os.s-<formal parameter>-seq)

```

The function *uniqueOperationName0* generates a unique *Operation-name* from the <operation name>, argument sort list, result sort and sort of the data type in which the operation is defined. Any algorithm that generates a unique *Name* is suitable. The one given here turns the parameters into a *TOKEN* string value that is made into a *Name*. The *TOKEN* string is a concatenation of the *TOKEN* string for the name and a list of *TOKEN* strings representing <identifier> items. Each *TOKEN* string for an <identifier> starts with separator ("##") that cannot appear in a <name>, therefore ensuring that every *Operation-name* is distinct any *Name* mapped simply from a <name>. The strings are in the following order: string for the result sort, string for the data type, and the strings for each argument sort (in order of the arguments).

NOTE – This algorithm is clearly inefficient and it is expected that analysis tools use a more efficient function to ensure unique *Operation-name* values.

```

uniqueOperationName0(n:<name>, argsorts:<sort>*, ressort:<sort>, datatype:<sort>):
  Operation-name =def
  mk-Name(
    n.s-TOKEN ^ // character string for <name>
    sortOpName0(ressort) ^ // string for the result sort
    sortOpName0(datatype) ^ // string for the data type sort
    < sortOpName0(argsorts[i]) | i in 1..argsorts.length > // strings for argument sorts
  )

```

The function *sortOpName0* generates the string for a <sort> to use in the functions *uniqueOperationName0* and *uniqueLiteralName0*. The identifier for the sort is determined. The string starts with the separator ("#") followed by a string for the full qualifier of the identifier followed by the string for the name of the identifier. The string for the full qualifier is enclosed by "<<" and ">>" and each path item is the string for the scope unit kind, followed by a space, followed by the string for name of the path item with the character "/" separating path items. That is, the fully qualified identifier string is the same as in the SDL-2010 concrete syntax.

```

sortOpName0(s:<sort>): TOKEN =def
let id = s.sortId0 in
"#" ^
"<<" ^
  < let pathitem = id.s-<path item>-seq[i] in
    case pathitem.s-<scope unit kind> of
      | package then "package"
      | system type then "system type"
      | system then "system"
      | block then "block"
      | block type then "block type"
      | process then "process"
      | process type then "process type"
      | state then "state"
      | state type then "state type"
      | procedure then "procedure"
      | signal then "signal"
      | type then "type"
      | operator then "operator"
      | method then "method"
      | interface then "interface"
      | composition then "composition"
    endcase // pathitem.s-<scope unit kind>
    ^ " "
    ^ pathitem.s-<name>.s-TOKEN
    ^ if i < pathitem.length then "/" else empty endif
  endlet // pathitem
  | i in 1..id.s-<path item>-seq[i].length
  >
  ^ ">>"
  ^ id.s-<name>.s-TOKEN
endlet // id

```

## F2.2.9.6 Data type constructors

### Concrete syntax

<data type constructor> = <literal list> | <structure definition> | <choice definition>

#### F2.2.9.6.1 Literals

### Abstract syntax

<i>Literal-signature</i>	::	<i>Literal-name</i> <i>Result</i> <i>Literal-natural</i>
<i>Literal-natural</i>	=	<i>Nat</i>

### Conditions on abstract syntax

$\forall ls1, ls2 \in \text{Literal-signature}: ls1.parentAS1 = ls2.parentAS1 \wedge ls1 \neq ls2 \Rightarrow$   
 $ls1.s\text{-Literal-natural} \neq ls2.Literal-natural$

Each *Literal-signature* in the *Literal-signature* set of a *Value-data-type-definition* shall have a different *Literal-natural*. See clause 12.1.6.1 *Abstract grammar* of [ITU-T Z.101].

## Concrete syntax

```
<literal list> :: [<visibility>] <literal signature>+
<literal signature> = <literal name> | <named number>
<named number> :: <literal name> <Natural<simple expression>
```

## Mapping to abstract syntax

```
| litlist = <literal list>(*,literals)
then
  let signatures = addNamedNumbers0(literals, 1) in
  let nopreamble = <operation preamble>(undefined, undefined) in
  let sort = litlist.parentAS0.parentAS0.identifier0 in
  let arg = mk-<argument>( in, mk-<anchored sort>(sort)) in
  let resbool = mk-<result>( predefinedId0("Boolean")) in
  let reslit = mk-<result>( mk-<anchored sort>(sort)) in
    { Mapping(signatures[i] | i ∈ 1..signatures.length )
  ∪ { Mapping(mk-<operation signature>(nopreamble, mk-<name>(""<"">"""), < arg , arg >, resbool)),
      Mapping(mk-<operation signature>(nopreamble, mk-<name>("">"">"""), < arg , arg >, resbool)),
      Mapping(mk-<operation signature>(nopreamble, mk-<name>("">=""">"""), < arg , arg >, resbool)),
      Mapping(mk-<operation signature>(nopreamble, mk-<name>(""<="""<"""), < arg , arg >, resbool)),
      Mapping(mk-<operation signature>(nopreamble, mk-<name>("first"), < >, reslit)),
      Mapping(mk-<operation signature>(nopreamble, mk-<name>("last"), < >, reslit)),
      Mapping(mk-<operation signature>(nopreamble, mk-<name>("pred"), < arg >, reslit)),
      Mapping(mk-<operation signature>(nopreamble, mk-<name>("succ"), < arg >, reslit)),
      Mapping(mk-<operation signature>(nopreamble, mk-<name>("num"), < arg , arg >,
        mk-<result>(predefinedId0("Natural")) ))
    } // operation signatures for generic operators
endlet // reslit
endlet // resbool
endlet // arg
endlet // sort
endlet // nopreamble
endlet // signatures
```

The following text is from clause 12.1.6.1 *Concrete grammar* of [ITU-T Z.101].

Each <literal name> in a <literal list> is given the lowest possible Natural simple expression value for the *Literal-natural* of the *Literal-signature* not occurring for any other <literal signature>s of the same <literal list>, considering the <literal name>s one by one from left to right. The result is, for example,

```
literals B, A = 2, C, D;
```

has  $B < C$  ,  $C < A$  ,  $A < D$  ,  $\text{num}(C) = 1$  ,  $\text{num}(D) = 3$

The following text is from clause 12.1.6.1 *Semantics* of [ITU-T Z.101].

Additional generic operators exist for a sort defined by a constructor that creates a *Literal-signature* set, as follows:

- an operator that gives the position of each data item in the ordering as the corresponding Natural simple expression value;
- operators that compare two data items with respect to the established ordering; and
- operators that return the first, last, next or previous data item in the ordering.

For a sort named S that is defined by a constructor that creates a *Literal-signature* set, there is a *Static-operation-signature* list equivalent to the following:

```
num ( S )    -> Natural;
"<" ( S, S ) -> Boolean;
">" ( S, S ) -> Boolean;
```

```

"≤" ( S, S ) -> Boolean;
"≥" ( S, S ) -> Boolean;
first      -> S;
last       -> S;
succ ( S ) -> S;
pred ( S ) -> S;

```

where Boolean is the predefined Boolean sort and Natural is the predefined Natural sort, and the parameters and the results correspond to an *Aggregation-kind* of **PART**.

The operator `num` returns the Natural simple expression value corresponding to the *Literal-natural* of the literal.

The comparison operators "`<`" ("`>`", "`≤`", "`≥`") represent the standard less-than (greater-than, less-or-equal-than, and greater-or-equal-than) comparison between the Natural simple expression values corresponding to each *Literal-natural* of the two literals. The operator `first` returns the first data item in the ordering (the literal with the lowest Natural simple expression value corresponding to the *Literal-natural*). The operator `last` returns the last data item in the ordering (the literal with the highest Natural simple expression value corresponding to the *Literal-natural*). The operator `pred` returns the preceding data item (that is, the literal with the highest *Literal-natural* that is less than the *Literal-natural* corresponding to the actual parameter), if one exists, or the same as the operator `last`, otherwise. The operator `succ` returns the successor data item (that is, the literal with the lowest *Literal-natural* that is greater than the *Literal-natural* corresponding to the actual parameter) in the ordering, if one exists, or the same as the operator `first`, otherwise.

```

| nn = <named number>(name, number) then
let sort = identifier0(parentASOfKind(nn, <data type definition>)) in
  mk-Literal-signature
    ( uniqueLiteralName0(name, sort),
      mk-Result(Mapping(sort, mk-Result-aggregation(PART))),
      mk-Literal-natural(Mapping(number)))
endlet // sort

```

The following text is from clause 12.1.6.1 *Concrete grammar* of [ITU-T Z.101].

The *Literal-name* is unique within the defining scope unit in the abstract syntax even if the corresponding `<literal name>` is not unique. The unique *Literal-name* is derived from:

- a) the `<literal name>`; plus
- b) the sort identifier of the data type definition in which the `<literal name>` is defined.

In a *Literal-signature*, the *Result* is the sort introduced by the `<data type definition>` defining the `<literal signature>`.

The Natural simple expression value of the `<Natural simple expression>` occurring in a `<named number>` represents the *Literal-natural* of the *Literal-signature*.

### Auxiliary functions

The function `uniqueLiteralName0` generates a unique *Literal-name* from the `<literal name>`, and sort of the data type in which the operation is defined. Any algorithm that generates a unique *Name* is suitable. The one given here turns the parameters into a *TOKEN* string value that is made into a *Name*. The *TOKEN* string is a concatenation of the *TOKEN* string for the name and a *TOKEN* string representing the sort `<identifier>`. The *TOKEN* string for the sort `<identifier>` starts with separator ("`#`") that cannot appear in a `<name>`, therefore ensuring that every *Literal-name* is distinct from any *Name* mapped simply from a `<name>`. The result is distinct from an *Operation-name* without parameters of the same sort, because an *Operation-name* includes a result sort.

```

uniqueLiteralName0(n:<name>, datatype:<sort>): Literal-name =def
mk-Name(

```

```

n.s-TOKEN  $\hat{\ } // character string for <name>
sortOpName0(datatype) // string for the data type sort
)$ 
```

The function *visibility0* provides the visibility of an operation or literal.

```

visibility0(s:<operation signature> $\cup$ <literal signature>):<visibility> =def
  if s  $\in$  <operation signature> then s.s-<visibility>
  else s.parentAS0.s-<visibility>

```

The function *addNamedNumbers0* changes the <literal signature> list (of a <literal list>) so that each <literal name> in turn is changed into a <named number>.

```

addNamedNumbers0(literals: <literal signature>*, i: NAT): <literal signature>* =def
  if i > literals.length then literals
  else
    addNamedNumbers0(
      if literals[i]  $\in$  <literal name> then changeLitsig0(literals, i) else literals endif,
      i+1)
  endif

```

The function *changeLitsig0* changes the item *i* of a <literal signature> list from a <literal name> into a <named number>.

```

changeLitsig0(literals: <literal signature>*, i: NAT): <literal signature>* =def
  headLitsigs0(literals, i)  $\hat{\ }
  < mk-<named number>(
    literals[i], mk-<operand5>( mk-<identifier>( predefinedQual0("Integer"),
      mk-<name>( nextNumber0(literals, 0))))
  ) >  $\hat{\ }
  tailLitsigs0(literals, i)$$ 
```

The function *headLitsigs0* produces a list of the items before item *i* of a <literal signature> list.

```

headLitsigs0(literals: <literal signature>*, i: NAT): <literal signature>* =def
  if i = 1 then empty
  else literals.head  $\hat{\ } headLitsigs0(literals.tail, i-1)$ 
```

The function *tailLitsigs0* produces a list of the items after item *i* of a <literal signature> list.

```

tailLitsigs0(literals: <literal signature>*, i: NAT): <literal signature>* =def
  if i = literals.length then empty
  else literals[i+1]  $\hat{\ } tailLitsigs0(literals, i+1)$ 
```

The function *nextNumber0* produces a *TOKEN* corresponding to the lowest available Natural number not occurring as a <simple expression> of any <named number> in the given <literal signature> list, and equal or higher than the initial value given. The function *natToIntToken* is in clause F2.2.1.6.5, Function definitions on AS0. The *simpleMapping* converts each <simple expression> into a *Constant-expression* that is evaluated by *value1* to produce an integer *TOKEN* compared with the current value of the counter *i* until one is found not already in the <literal signature> list.

```

nextNumber0(literals: <literal signature>*, i: NAT): TOKEN =def
  if ( $\neg \exists n \in$  <named number> : n in literals
   $\wedge$  ( n.s-<simple expression>.simpleMapping.value1.intTokenToNat = i))
  then
    i.natToIntToken
  else
    nextNumber0(literals, i+1)
  endif

```

## F2.2.9.6.2 Structure data types

### Concrete syntax

<structure definition> :: [<visibility>] <field list>  
<field list> = <field>+  
<field> =  
    <optional field> | <mandatory field>  
<optional field> :: <fields of sort>  
<mandatory field> :: <fields of sort> [<field default initialization>]  
<field default initialization> :: <constant expression>  
<fields of sort> :: [<visibility>] <field of kind>+ <field sort>  
<field of kind> :: <aggregation kind> <field name>  
<field sort> = <sort>

### Conditions on concrete syntax

$\forall sd \in \langle \text{structure definition} \rangle: sd.\text{fieldNameList0}.\text{length} = |sd.\text{fieldNameList0}.\text{toSet}|$

Each <field name> of a structure sort shall be different from every other <field name> of the same <structure definition>.

### Transformations

< <optional field>( <fields of sort>(vis, <f>  $\hat{}$  rest, sort)) > **provided** rest  $\neq$  empty =5=>  
    < **mk**-<optional field>( <fields of sort>(vis, <f>, sort)),  
    **mk**-<optional field>( <fields of sort>(vis, rest, sort)) >  
  
< <mandatory field>( <fields of sort>(vis, <f>  $\hat{}$  rest, sort), init) > **provided** rest  $\neq$  empty =5=>  
    < **mk**-<mandatory field>( <fields of sort>(vis, <f>, sort), init),  
    **mk**-<mandatory field>( <fields of sort>(vis, rest, sort), init) >

A <field list> containing a <field> that has a <fields of sort> with an <field of kind> list is derived concrete syntax where this <field> is replaced by a list of <field>s separated by <end>, one for each <field of kind> in the order of occurrence of each <field of kind>. Each <field> in the replacement list has a <fields of sort> with same <visibility> and <field sort> as the original <fields of sort>. Each <field> in the replacement list is **optional** if the original <field> was **optional**, or has the <field default initialization> of the original <field> if there was one. See clause 12.1.6.2 *Model* of [ITU-T Z.104].

<operator application>(ident, params = first  $\hat{}$  <param>  $\hat{}$  last)  
    **provided** ident.s-<operation name>.s-TOKEN = "Make"  $\wedge$   
    param = undefined  $\wedge$   
     $\exists sd(*, fields) \in \langle \text{structure definition} \rangle: sd.\text{parentAS0}.\text{parentAS0} =$   
        parentAS0ofKind(ident.refersto0, <data type definition>)  $\wedge$   
        expandfieldsSt0(fields)[first.length + 1]  $\in$  <mandatory field>  $\wedge$   
        expandfieldsSt0(fields)[first.length + 1].s-<field default initialization>  $\neq$  undefined  
=8=>  
    **mk**-<method application>( **mk**-<operator application>( ident, params),  
    **mk**-<identifier>(parentAS0ofKind(ident.refersto0, <data type definition>).fullQualifier0,  
    **mk**-<name>(sd.fieldNameList0[first.length + 1].s-TOKEN + "Modify")),  
    < expandfieldsSt0(fields)[first.length + 1].s-<field default initialization>>)

A Make operation with a non-empty *Formal-argument* list creates a new structure and associates each field with the result of the corresponding formal parameter, or if no actual argument is given for the field, the default initialization for that field, or "undefined" if there is no default initialization for the field. See clause 12.1.6.2 *Semantics* of [ITU-T Z.101].

## Mapping to abstract syntax

The mapping to abstract syntax for <structure definition> as part of the mapping is a <data type definition body> in clause F2.2.9.2 Data type definition. The description of the mapping from clause 12.1.6.2 *Concrete grammar* of [ITU-T Z.101] items (a), (c), (d), (e) and (f), and clause 12.1.6.2 *Concrete grammar* item (b) of [ITU-T Z.104] is in clause F2.2.9.2 Data type definition.

## Auxiliary functions

The function *expandfieldsSt0* expands a list of structure fields to produce a new list where each field contains one name.

```
expandfieldsSt0(fl: {<optional field> ∪ <mandatory field>}*): {<optional field> ∪ <mandatory field>}* =def
if fl.length = 0 then undefined
elseif fl.length = 1 then
  if fl.head ∈ <optional field> then
    < mk-<optional field>(
      mk-<fields of sort>(
        fl.head.s-<fields of sort>.s-<visibility>,
        < fl.head.s-<fields of sort>.s-<field of kind>-seq.head >,
        fl.head.s-<fields of sort>.s-<field sort>
      ) )>
  else
    < mk-<mandatory field>(
      mk-<fields of sort>(
        fl.head.s-<fields of sort>.s-<visibility>,
        < fl.head.s-<fields of sort>.s-<field of kind>-seq.head >,
        fl.head.s-<fields of sort>.s-<field sort>,
        fl.head.s-<field default initialization>
      ) >
    endif ^
    if fl.head.s-<fields of sort>.s-<field of kind>-seq.length = 1
    then empty
    else
      expandfieldsSt0(
        if fl.head ∈ <optional field> then
          < mk-<optional field>(
            mk-<fields of sort>(
              fl.head.s-<fields of sort>.s-<visibility>,
              fl.head.s-<fields of sort>.s-<field of kind>-seq.tail,
              fl.head.s-<fields of sort>.s-<field sort>
            ) )>
          else
            < mk-<mandatory field>(
              mk-<fields of sort>(
                fl.head.s-<fields of sort>.s-<visibility>,
                fl.head.s-<fields of sort>.s-<field of kind>-seq.tail,
                fl.head.s-<fields of sort>.s-<field sort>,
                fl.head.s-<field default initialization>
              ) >
            endif
          else
            expandfieldsSt0(< fl.head >) ^ expandfieldsSt0(fl.tail)
          endif
        )
    endif
  endif

```

The function *fieldNameList0* gives the list of structure field or choice names for a structure definition or choice definition in the order the fields appear in the definition.

```
fieldNameList0(d*,lst):<structure definition>∪<choice definition>): <name>* =def
if d ∈ <structure definition>
then // structure definition
  let dtd = parentASOfKind(d, <data type definition>) in // enclosing data type definition

```

```

if dtd.s-<data type specialization> ≠ undefined // inheritance – allowed for structure but not choice
then // assumes the specialization has no renaming and no context parameters
  let basedef = dtd.s-<data type specialization>.s-<identifier>.refersto0 in // base data type definition
  fieldNameListSt0(basedef.s-<data type definition body>.s-<data type constructor>)
  endlet // basedef
else empty // nothing inherited
endif // inheritance
~

fieldNameListSt0(lst)
endlet // dtd
else fieldNameListCh0(lst) // choice definition – inheritance not allowed
endif // structure or choice

```

The function *fieldNameListSt0* gives the list of structure field names from a list of fields in the order the fields appear in the list.

```

fieldNameListSt0(fl: {<optional field> ∪ <mandatory field>}*): <name>* =def
if fl.length = 0 then undefined
elseif fl.length = 1 then
  <fl.head.s-<fields of sort>.s-<field of kind>-seq.head.s-<name> > ^
  if fl.head.s-<fields of sort>.s-<field of kind>-seq.length = 1
  then empty
  else fieldNameListSt0(fl.head.s -<fields of sort>.s-<field of kind>-seq.tail)
  endif
else
  fieldNameListSt0(<fl.head>)^fieldNameListSt0(fl.tail)
endif

```

The function *fieldNameListCh0* gives the list of choice field names from a list of fields in the order the fields appear in the list.

```

fieldNameListCh0(cl: <choice of sort>*): <name>* =def
if cl.length = 0 then undefined
elseif cl.length = 1 then
  <cl.head.s-<choice of sort>.s-<field of kind>-seq.head.s-<name> > ^
  if cl.head.s-<choice of sort>.s-<field of kind>-seq.length = 1
  then empty
  else fieldNameListCh0(cl.head.s -<choice of sort>.s-<field of kind>-seq.tail)
  endif
else
  fieldNameListCh0(<cl.head>)^fieldNameListCh0(cl.tail)
endif

```

The function *fieldSortList0* gives the list of structure field sorts from a list of fields in the order the fields appear in the list.

```

fieldSortList0(d(*lst): <structure definition> ∪ <choice definition>): <sort>* =def
if d ∈ <structure definition>
then // structure definition
  let dtd = parentAS0ofKind(d, <data type definition>) in // enclosing data type definition
  if dtd.s-<data type specialization> ≠ undefined // inheritance – allowed for structure but not choice
  then // assumes the specialization has no renaming and no context parameters
    let basedef = dtd.s-<data type specialization>.s-<identifier>.refersto0 in // base data type definition
    fieldSortList0(basedef.s-<data type definition body>.s-<data type constructor>)
    endlet // basedef
  else empty // nothing inherited
  endif // inheritance
  ~

  fieldSortListSt0(lst)
  endlet // dtd
else fieldSortListCh0(lst) // choice definition – inheritance not allowed
endif // structure or choice

```

The function *fieldSortListSt0* gives the list of structure field sorts from a list of fields in the order the fields appear in the list.

```

fieldSortListSt0(fl: {<optional field> ∪ <mandatory field>}*): <name>* =def
if fl.length = 0 then undefined
elseif fl.length = 1 then
  <fl.head.s-<fields of sort>.s-<field sort> > ^
  if fl.head.s-<fields of sort>.s-<field of kind>-seq.length = 1
  then empty
  else fieldSortListSt0(fl.head.s -<fields of sort>.s-<field of kind>-seq.tail)
  endif
else
  fieldSortListSt0(<fl.head >)^ fieldSortListSt0(fl.tail)
endif

```

The function *fieldSortListCh0* gives the list of choice sorts from a list of fields in the order the fields appear in the list.

```

fieldSortListCh0(cl: <choice of sort>*): <name>* =def
if cl.length = 0 then undefined
elseif cl.length = 1 then
  <cl.head.s-<choice of sort>.s-<field sort> > ^
  if cl.head.s-<choice of sort>.s-<field of kind>-seq.length = 1
  then empty
  else fieldSortListCh0(cl.head.s -<choice of sort>.s-<field of kind>-seq.tail)
  endif
else
  fieldSortListCh0(<cl.head >)^ fieldSortListCh0(cl.tail)
endif

```

### F2.2.9.6.3 Choice data types

#### Concrete syntax

```

<choice definition> ::  [<visibility>] [ <choice list> ]
<choice list> = <choice of sort>+
<choice of sort> :: [<visibility>] <field of kind>+ <field sort>

```

#### Conditions on concrete syntax

$$\forall cd \in \langle \text{choice definition} \rangle: cd.\text{fieldNameList0}.\text{length} = |cd.\text{fieldNameList0}.\text{toSet}|$$

Each <field name> of a choice sort shall be different from every other <field name> of the same <choice definition>. See clause 12.1.6.3 *Concrete grammar* of [ITU-T Z.101].

#### Transformations

```

< <choice of sort>(vis, <c> ^ rest, sort) >
provided rest ≠ empty
=5=>
< mk-<choice of sort>(vis, <c>, sort), mk-<choice of sort>(vis, rest, sort) >

```

A <choice list> containing a <choice of sort> with an <aggregation kind> <field name> pair list is derived concrete syntax where this <choice of sort> is replaced by a list of <choice of sort> items separated by <end>, one for each <aggregation kind> <field name> pair in the order of occurrence of each <aggregation kind> <field name> pair. Each <choice of sort> in the replacement list has the same <visibility> and <field sort> as the original <choice of sort>. See clause 12.1.6.3 *Model* of [ITU-T Z.104].

## Mapping to abstract syntax

The mapping to abstract syntax for <choice definition> as part of the mapping is a <data type definition body> in clause F2.2.9.2 Data type definition. The description of the mapping from clause 12.1.6.3 *Concrete grammar* of [ITU-T Z.101] is in clause F2.2.9.2 Data type definition.

### F2.2.9.7 Behaviour of operations

#### Concrete syntax

<operation definition item> =  
    <operation definition> | <operation reference> | <external operation definition>  
  
<operation reference> :: <operation kind> <operation signature>  
  
<external operation definition> :: <operation kind> <operation signature>  
  
<operation definition> ::  
    <package use clause>\* <operation heading> <entity in operation>\*  
    { <operation body> | <statements> }  
  
<operation heading> ::  
    <operation kind> <operation preamble> [ <qualifier> ] <operation name>  
    <formal operation parameters> [ <operation result> ]  
  
<formal operation parameters> = <formal variable parameters>\*  
  
<operation kind> :: **operator** | **method**  
  
<operation identifier> :: [ <qualifier> ] <operation name>  
  
<entity in operation> =  
    <data definition>  
    | <variable definition>  
    | <select definition>  
  
<operation body> ::  
    <start> { <free action> }\*  
  
<operation result> :: <result aggregation> [ <variable<name>> ] <sort>

<operation definition> is an alternative textual concrete syntax to <operation diagram> and therefore defines a scope unit. See clause 6 of [ITU-T Z.106].

#### Conditions on concrete syntax

$\forall opRef \in \langle \text{operation reference} \rangle :$   
     $(opRef.s \langle \text{operation signature} \rangle .s \langle \text{arguments} \rangle = \text{undefined} \vee$   
     $opRef.s \langle \text{operation signature} \rangle .s \langle \text{result} \rangle = \text{undefined}) \Rightarrow$   
     $(\forall opRef1 \in \langle \text{operation reference} \rangle :$   
         $opRef1 \neq opRef \wedge opRef1.parentAS0 = opRef1.parentAS0 \Rightarrow opRef1.name0 \neq opRef.name0)$

<arguments> and <result> of the <operation signature> in an <operation reference> are allowed to be omitted if there is no other <operation reference> within the same sort of data that has the same name. In this case, the referenced <operation definition> is identified simply by its name. The <operation reference> enables the referenced <operation definition> to be located, so that it is possible to map the concrete definition to the enclosing data type definition in the logical hierarchy in the abstract grammar. Modified from clause 8.2 *Concrete grammar* of [ITU-T Z.101].

$\forall opDef \in \langle \text{external operation definition} \rangle :$   
     $(opDef.s \langle \text{operation signature} \rangle .s \langle \text{arguments} \rangle = \text{undefined} \wedge$   
     $opDef.s \langle \text{operation signature} \rangle .s \langle \text{result} \rangle = \text{undefined}) \Rightarrow$   
     $\neg (\exists opDef1 \in \langle \text{external operation definition} \rangle \setminus \{ opDef \} :$   
         $opDef1.parentAS0 = opDef1.parentAS0 \wedge$   
         $opDef1.s \langle \text{operation signature} \rangle .s \langle \text{name} \rangle = opDef1.s \langle \text{operation signature} \rangle .s \langle \text{name} \rangle)$   
     $\wedge (\exists opSig \in \langle \text{operation signature} \rangle :$   
         $opDef.parentAS0 = opSig.parentAS0 \wedge$   
         $opDef.s \langle \text{operation signature} \rangle .s \langle \text{name} \rangle = opSig.name0)$

It is allowed to omit <arguments> and <result> in <external operation definition> if there is no other <external operation definition> within the same sort which has the same name, and an <operation signature> is present. In this case, the <arguments> and the <result> are derived from the <operation signature>. See clause 12.1.7 *Concrete grammar* of [ITU-T Z.104].

$$\forall od \in \langle \text{operation definition} \rangle: \exists ! os \in \langle \text{operation signature} \rangle: \\ od.name0 = os.name0 \wedge od.parentAS0 = os.parentAS0 \Rightarrow isSameOperationAndSignature0(od, os)$$

In an <operation signature> of <operation signatures> there shall be one and only one corresponding definition (<operation reference> or <external operation definition>) in the <operation definitions> of the <operations>. See clause 12.1.1 *Concrete grammar* of [ITU-T Z.104].

$$\forall os \in \langle \text{operation signature} \rangle: \exists ! od \in (\langle \text{operation reference} \rangle \cup \langle \text{external operation definition} \rangle): \\ od.parentAS0 = os.parentAS0 \wedge od.name0 = os.name0 \wedge isSameOperationAndSignature0(od, os)$$

For an <operation signature> of <operation signatures> there shall be one and only one corresponding definition (<operation reference> or <external operation definition>) in the <operation definitions> of the <operations>. See clause 12.1.1 *Concrete grammar* of [ITU-T Z.104].

$$\forall bs \in \langle \text{operation body} \rangle \cup \langle \text{statement} \rangle: parentAS0ofKind(bs, \langle \text{operation definition} \rangle) \neq undefined \Rightarrow \\ (\neg \exists ie \in \langle \text{imperative expression} \rangle: isAncestorAS0(bs, ie)) \wedge \\ (\forall id \in \langle \text{identifier} \rangle: id.idKind0 \notin \{\mathbf{synonym}, \mathbf{procedure}\} \wedge isAncestorAS0(bs, id) \Rightarrow \\ isDefinedIn0(getEntityDefinition0(id, id.idKind0), \\ parentAS0ofKind(bs, \langle \text{operation definition} \rangle)))$$

The <operation body> and <statement>s in <operation definition> shall contain neither an <imperative expression> nor an <identifier> defined outside the enclosing <operation definition>, except for <synonym identifier>s, <operation identifier>s, <literal identifier>s and <sort>s. Derived from clauses 12.1.7 *Concrete grammar* of [ITU-T Z.101] and 12.1.7 *Concrete grammar* of [ITU-T Z.104].

## Transformations

<operations>(opsigs, opdefs)

**provided**

$\exists opdef$  in opdefs: (

$opdef \in \langle \text{operation definition} \rangle \wedge$

**if** opdefs[i].s-<operation heading>.s-<operation kind> = **operator**

**then**

**if** opsigs.s-<operator list>  $\neq$  undefined

**then**  $\neg \exists opsig$  in opsigs.s-<operator list>:

$isSameOperationSignature0(operationSignature0(opdef), opsig)$

**else true**

**endif** // operator

**else** // method

**if** opsigs.s-<method list>  $\neq$  undefined

**then**  $\neg \exists opsig$  in opsigs.s-<method list>:

$isSameOperationSignature0(operationSignature0(opdef), opsig)$

**else true**

**endif** // method

**endif true** // operator or method

) // exists opdef in opdefs such that no corresponding signature in opsigs

=8=>

**mk**-<operations>(

**mk**-<operation signatures>(

**mk**-<operator list>(

**if** opsigs.s-<operator list>  $\neq$  undefined **then** opsigs.s-<operator list> **else empty endif** ^

< **mk**-<operation signature>(operationSignature0(opdef[i])) :

$i \in 1..opdefs.length \wedge$

**if** opsigs.s-<operator list>  $\neq$  undefined

**then**  $\neg \exists opsig$  in opsigs.s-<operator list>:

$isSameOperationSignature0(operationSignature0(opdef[i]), opsig)$

```

        else true
      endif
    > // list of new operator signatures
  ), // operator list
  mk-<method list>(
    if opsigs.s-<method list> ≠ undefined then opsigs.s-<operator list> else empty endif ^
    < mk-<operation signature>(operationSignature0(opdef[i])) :
      i ∈ 1..opdefs.length ^
      if opsigs.s-<method list> ≠ undefined
      then ¬∃ opsig in opsigs.s-<operator list>:
        isSameOperationSignature0(operationSignature0(opdef[i]), opsig)
      else true
      endif
    > // list of new method signatures
  ), // method list
), // operation signatures
opdefs
)

```

For every <operation definition> which does not have a corresponding <operation signature>, an <operation signature> is constructed. See clause 12.1.7 *Model* of [ITU-T Z.104].

```

eod = <external operation definition>(kind, <operation signature>(pre, name, undefined, undefined))
=8=>
let opSig = take({os ∈ <operation signature> : eod.parentAS0 = opSig.parentAS0 ∧ os.name0 = name}) in
mk-<external operation definition>( kind,
  mk-<operation signature>(pre, name, opSig.s-<arguments>, opSig.s-<result>))
endlet

```

It is allowed to omit <arguments> and <result> in <external operation definition>. In this case, the <arguments> and the <result> are derived from the <operation signature>. See clause 12.1.7 *Concrete grammar* of [ITU-T Z.104].

```

od.operatorProcedureId
provided
  od ∈ <operation definition>
  ∧ od.operatorProcedureId = undefined
=11=>
(operatorProcedureId \{( od, undefined )})
∪ { ( od, mk-<identifier>( od.fullQualifier, newName) ) }

```

## Mapping to abstract syntax

The following paragraphs describe the mapping of operation definitions to procedure definitions in the enclosing data type definition. The function *procsForOps* below determines the set of procedures for the operations and is invoked in the mapping of F2.2.9.2 to insert the procedure definitions into the data type.

An <operation definition> represents a *Procedure-definition* in the *Procedure-definition-set* of the directly enclosing *Data-type-definition*. The *Procedure-name* of the *Procedure-definition* is an anonymous unique name, and the *Procedure-definition* is associated with the *Operation-signature* by the *Procedure-identifier* in the *Operation-signature*. The <formal operation parameters> list for the operator represents the *Procedure-formal-parameter* list of the *Procedure-definition* in the same way as the formal parameters for a procedure. The <operation result> represents the *Result* of the *Procedure-definition*; therefore the <result aggregation> represents the *Result-aggregation*. The components of the <operation body area> are used in the same way as the components of a <procedure body area> to represent the *Data-type-definition-set*, *Syntype-definition-set*, *Variable-definition-set*, *Procedure-definition-set* and *Procedure-graph* of the *Procedure-definition*. See clause 12.1.7 *Concrete grammar* of [ITU-T Z.101].

If the <operation kind> is **operator**, each item in the <formal operation parameters> represents an item (in the same order) in the *Procedure-formal-parameter* list of the *Procedure-definition* for the operator. If the <operation kind> is **method**, the first item in the *Procedure-formal-parameter* list of the *Procedure-definition* for the method is an *Inout-parameter* with an anonymous *Variable-name* and a *Sort-reference-identifier* that identifies the sort for the data type in which the method is defined. Each item in the <formal operation parameters> of a method represents a subsequent item (in the same order) in the *Procedure-formal-parameter* list of the *Procedure-definition* for the method. See clause 12.1.7 *Concrete grammar* of [ITU-T Z.104].

If the <operation heading> begins with the keyword **operator**, then <operation definition> defines the behaviour of an operator. If the <operation heading> begins with the keyword **method**, then <operation definition> defines the behaviour of a method. Whether an operation is an operator or method is part of the operation signature and therefore part of the identity of the operation. See clause 12.1.7 *Concrete grammar* of [ITU-T Z.104].

If an operation contains informal text, the interpretation of expressions involving application of the corresponding operation is not formally defined by the Specification and Description Language but is determined from the informal text by the interpreter. If informal text is specified, a complete formal specification has not been given in the Specification and Description Language. See clause 12.1.7 *Model* of [ITU-T Z.104].

### Auxiliary functions

The Boolean function *isSameOperationAndSignature0* is true if the given operation is an <operation definition> has the same result as the given signature, both have the same number of parameters and each the parameters of the operation has the same sort and parameter kind as the given signature.

```

isSameOperationAndSignature0(od: <operation definition>∪<external operation definition>,
  os: <operation signature> ): BOOLEAN =def
if od ∈ <operation definition> then
  let seq1 = od.operationFormalparameterList0 in
  let seq2 = os.operationSignatureParameterList0 in
  (od.s-<operation heading>.s-<operation result> ≠ undefined ⇒
    isSameResult0(od.s-<operation heading>.s-<operation result>, os.s-<result>) ∧
    (seq1≠empty ⇒
      seq1.length = seq2.length ∧
      (∀i∈1..seq1.length: isSameSort0(seq1[i].parentAS0.s-<sort>, seq2[i].s-<sort>) ∧
        seq1[i].parentAS0.s-<parameter kind>= seq2[i].s-<parameter kind>)))
  endlet // seq2
  endlet // seq1
else // od ∈ <external operation definition>
  od.s-<operation signature> = os
endif

```

The function *operationFormalparameterList0* gets the list of names of the formal parameters of an operation definition.

```

operationFormalparameterList0(od: <operation definition>): <name>* =def
< opl.s-<parameters of sort>.s-<name>-seq |
  opl in od.s-<operation heading>.s-<formal variable parameters>-seq >

```

The function *idKind0* determines the entity kind of an <identifier> according to its syntactic position. For an <identifier> in an <actual context parameter>, the result is the entity kind of the formal context parameter which matches the list position of the actual parameter in the formal context parameter list of the base type <identifier> of the enclosing <type expression>. For a base type <identifier> in an <type expression>, the result is determined by context of the <type expression> and in most cases is **sort**. For an <identifier> in an <encoding path>, the result is determined by number of items in the <encoding expression>: if there is one item it is a channel or gate, and if there are two items the

<identifier> gives an interface for the first item and the literal in the `Encoding` data type for the second item.

```

idKind0(i: <identifier>): ENTITYKIND0 =def
case i.parentAS0 of
| <active agents expression> then agent
| a=<actual context parameter> then
  take({f ∈ <formal context parameter>:
    isContextParameterCorresponded0(f, a)
    ∧ parentAS0ofKind(f, ENTITYDEFINITION0) = a.parentAS0.baseType0
  }).entityKind0
| <agent constraint atleast> then agent type
| <agent constraint exactly> then agent type
| <agent type context parameter> then agent type
| <any expression> then sort
| <as channel> then channel
| <as gate> then gate
| <as signal> then signal
| <assignment> then variable
| <block type reference> then block type
| <channel endpoint> then
  if getEntityDefinition0(i, agent) ≠ undefined then agent else state endif
| <channel to channel connection> then channel
| <composite state type reference> then state type
| <compositestate type context parameter> then state type

    makeProcedureBody(od.s-implicit)
  )) // internal procedure definition, Mapping
: od ∈ <operation definition>
  ∧ od in dtd.s-<data type definition body>.s-<operations>.s-<operation definitions>
}

```

## F2.2.9.8 Additional data definition constructs

### F2.2.9.8.1 Name class mapping

Name class mapping is defined in clause A.2.10 of [ITU-T Z.104] and is intended for use only to define SDL-2010 language features and is not part of the SDL-2010 language itself. It is no longer formally described in Annex F.

### F2.2.9.8.2 Restricted visibility

#### Concrete syntax

<visibility> = **public** | **protected** | **private**

#### Conditions on concrete syntax

See clause 12.1.8.4 *Concrete grammar* of [ITU-T Z.104].

$$\forall d \in \langle \text{data type definition} \rangle: d.\text{specialization0} \neq \text{undefined} \Rightarrow$$

$$(\forall \text{cons} \in \langle \text{data type constructor} \rangle:$$

$$\text{cons.surroundingScopeUnit0} = d \Rightarrow \text{cons.s-visibility} = \text{undefined})$$

A <visibility> keyword shall not precede a <literal list>, <structure definition>, or <choice definition> in a <data type definition> containing <data type specialization>.

$$\forall \text{os} \in \langle \text{operation signature} \rangle:$$

$$\text{os.virtuality0} \in \{\text{redefined}, \text{finalized}\} \Rightarrow \text{os.visibility0} = \text{undefined}$$

A <visibility> keyword shall not be used in an <operation signature> that redefines an inherited operation signature.

#### Transformations

$$\langle \text{operation preamble} \rangle(\text{virt}, \text{vis}) \text{ provided } \text{vis} \neq \text{undefined}$$

$$=2=> \langle \text{operation preamble} \rangle(\text{virt}, \text{undefined})$$

$$\langle \text{literal list} \rangle(\text{vis}, \text{sigs}) \text{ provided } \text{vis} \neq \text{undefined}$$

$$=2=> \langle \text{literal list} \rangle(\text{undefined}, \text{sigs})$$

$$\langle \text{structure definition} \rangle(\text{vis}, \text{fields}) \text{ provided } \text{vis} \neq \text{undefined}$$

$$=2=> \langle \text{structure definition} \rangle(\text{undefined}, \text{fields})$$

$$\langle \text{fields of sort} \rangle(\text{vis}, \text{fields}, \text{sort}) \text{ provided } \text{vis} \neq \text{undefined} =2=> \langle \text{fields of sort} \rangle(\text{undefined}, \text{fields}, \text{sort})$$

$$\langle \text{choice definition} \rangle(\text{vis}, \text{fields}) \text{ provided } \text{vis} \neq \text{undefined} =2=> \langle \text{choice definition} \rangle(\text{undefined}, \text{fields})$$

$$\langle \text{choice of sort} \rangle(\text{vis}, \text{fields}, \text{sort}) \text{ provided } \text{vis} \neq \text{undefined}$$

$$=2=> \langle \text{choice of sort} \rangle(\text{undefined}, \text{fields}, \text{sort})$$

If a <literal signature> or <operation signature> contains the keyword **public** in <visibility>, this is derived syntax for a signature having no protection. See clause 12.1.9 of [ITU-T Z.104].

#### Auxiliary functions

The function *isPrivate0* determines if a <literal signature> or an <operation signature> is private.

$$\text{isPrivate0}(s: \langle \text{literal signature} \rangle \cup \langle \text{operation signature} \rangle): \text{BOOLEAN} =_{\text{def}}$$

( *s.visibility0* = **private** )

The function *isPublic0* determines if a <literal signature> or an <operation signature> is public.

*isPublic0* (*s*: <literal signature> ∪ <operation signature>): *BOOLEAN* =<sub>def</sub>  
( *s.visibility0* ≠ **private** ) ∧ ( *s.visibility0* ≠ **protected** )

### F2.2.9.8.3 Syntypes

#### Abstract syntax

*Syntype-definition* :: *Syntype-name*  
*Parent-sort-identifier*  
*Range-condition*  
[ *Default-initialization* ]

*Parent-sort-identifier* = *Sort-identifier*

#### Concrete syntax

<syntype> = <syntype><identifier>

<syntype definition> ::  
<package use clause> \*  
{ <syntype definition syntype> | <syntype definition data type> }

<syntype definition syntype> ::  
<syntype><name> <parent sort identifier>  
[<default initialization>] [<constraint>]

<syntype definition data type> ::  
<type preamble> <data type heading> [<data type specialization>]  
<data type definition body> <constraint>

<parent sort identifier> = <sort>

#### Transformations

< <syntype definition>(uses,  
<syntype definition data type>(preamble,  
<data type heading>(kind, name, params, vconstr), spec, body, constr)) >  
=8=>  
**let** *nn* = *newName* **in**  
  < **mk**-<syntype definition>(uses,  
    **mk**-<syntype definition syntype>(name, **mk**-<identifier>(empty, nn), undefined, constr)),  
    **mk**-<data type definition>(uses, preamble, **mk**-<data type heading>(kind, nn, params, vconstr),  
      spec, body) >  
**endlet** // *newName*

A <syntype definition data type> is distinguished from a <data type definition> by the inclusion of a <constraint>. Such a <syntype definition> is shorthand for introducing a <data type definition> with an anonymous name without the <constraint>, followed by a <syntype definition> with <syntype definition syntype> based on this anonymously named sort and including <constraint>. See clause 12.1.8.1 *Model* of [ITU-T Z.104].

#### Mapping to abstract syntax

| <syntype definition>(\*, <syntype definition syntype>(name, parent, \*, constr)) **then**  
  **mk**-*Syntype-definition*(*Mapping*(name), *Mapping*(parent), *Mapping*(constr))

### F2.2.9.8.4 Constraint

#### Abstract syntax

*Range-condition* :: *Condition-item-set*

*Condition-item* = *Open-range* | *Closed-range* | *Size-constraint*

<i>Open-range</i>	::	<i>Operation-identifier Constant-expression</i>
<i>Closed-range</i>	::	<i>Constant-expression Constant-expression</i>
<i>Size-constraint</i>	::	<i>Operation-identifier</i> { <i>Open-range</i>   <i>Closed-range</i> }*

## Concrete syntax

<constraint> = <range condition> | <size constraint>  
 <range condition> = <range>+  
 <range> = <closed range> | <open range>  
 <open range> = <constant> | <open range with operator>  
 <open range with operator> ::  
 { <equals sign> | <not equals sign> | <less than sign> | <greater than sign> |  
 <less than or equals sign> | <greater than or equals sign> } <constant>  
 <constant> = <constant expression>  
 <closed range> :: <constant> <constant>  
 <size constraint> :: <range condition>

## Conditions on concrete syntax

The text items below for conditions are from clause 12.1.8.2 of [ITU-T Z.101].

$$\forall sd \in \langle \text{syntype definition} \rangle: sd.\mathbf{s}\text{-implicit.s}\text{-}\langle \text{constraint} \rangle \in \langle \text{range condition} \rangle \Rightarrow$$

$$(\mathbf{let} \text{ rc} = sd.\mathbf{s}\text{-implicit.s}\text{-}\langle \text{constraint} \rangle \mathbf{in}$$

$$(\forall sym \in \langle \text{less than sign} \rangle: isAncestorAS0(rc, sym) \Rightarrow isDefinedSym0(sd, "" < "")) \wedge$$

$$(\forall sym \in \langle \text{greater than sign} \rangle: isAncestorAS0(rc, sym) \Rightarrow isDefinedSym0(sd, "" > "")) \wedge$$

$$(\forall sym \in \langle \text{less than or equals sign} \rangle: isAncestorAS0(rc, sym) \Rightarrow isDefinedSym0(sd, "" \leq "")) \wedge$$

$$(\forall sym \in \langle \text{greater than or equals sign} \rangle: isAncestorAS0(rc, sym) \Rightarrow isDefinedSym0(sd, "" \geq ""))$$

$$\mathbf{endlet})$$

The symbol "<" shall only be used in the concrete syntax of the <range condition> if that symbol has been defined with an <operation signature>: "<" ( P, P ) -> <<package Predefined>>Boolean; where P is the sort of the syntype, and similarly for the symbols ("<=", ">", ">=", respectively).

$$\forall sd \in \langle \text{syntype definition} \rangle: sd.\mathbf{s}\text{-implicit.s}\text{-}\langle \text{constraint} \rangle \in \langle \text{range condition} \rangle \Rightarrow$$

$$\forall cr \in \langle \text{closed range} \rangle:$$

$$isAncestorAS0(sd.\mathbf{s}\text{-implicit.s}\text{-}\langle \text{range condition} \rangle, cr) \Rightarrow isDefinedSym0(sd, "" \leq "")$$

A <closed range> shall only be used if the symbol "<=" is defined with an <operation signature>: "<=" ( P, P ) -> <<package Predefined>>Boolean; where P is the sort of the syntype.

$$\forall sd \in \langle \text{syntype definition} \rangle: \forall rc \in \langle \text{range condition} \rangle: \forall ce \in \langle \text{constant expression} \rangle:$$

$$isAncestorAS0(rc, ce) \wedge rc.\text{surroundingScopeUnit0} = sd \Rightarrow isSameSort0(ce.\text{staticSort0}, sd.\text{identifier0})$$

A <constant expression> in a <range condition> shall have the same sort as the sort of the syntype.

$$\forall sd \in \langle \text{syntype definition} \rangle: \forall sc \in \langle \text{size constraint} \rangle:$$

$$sc = sd.\mathbf{s}\text{-implicit.s}\text{-}\langle \text{constraint} \rangle \Rightarrow isDefinedSym0(sd, \text{"length"})$$

A <size constraint> shall only be used in the concrete syntax of the <range condition> if the symbol length has been defined with an <operation signature>: length (in P ) -> <<package Predefined>>Natural; where P is the sort of the syntype.

## Mapping to abstract syntax

$$| r = \langle \text{range condition} \rangle \mathbf{then}$$

$$\mathbf{mk}\text{-Range-condition}(\mathbf{if} \text{ item} \in \text{EXPRESSION0} \mathbf{then} \mathbf{mk}\text{-Open-range}(\text{rangeOperator}(r, "" = ""), \text{Mapping}(\text{item}))$$

$$\mathbf{else} \text{Mapping}(\text{item}) \mathbf{endif} : \text{item in } r \text{ > .toSet})$$

```

| r = <open range with operator>(<equals sign>(), const) then
  mk-Open-range(rangeOperator(r, ""="" ), Mapping(const))

| r = <open range with operator>(<not equals sign>(), const) then
  mk-Open-range(rangeOperator(r, ""!=""), Mapping(const))

| r = <open range with operator>(<less than sign>(), const) then
  mk-Open-range(rangeOperator(r, ""<"" ), Mapping(const))

| r = <open range gen with operator>(<greater than sign>(), const) then
  mk-Open-range(rangeOperator(r, "">"" ), Mapping(const))

| r = <open range with operator>(<less than or equals sign>(), const) then
  mk-Open-range(rangeOperator(r, "<="), Mapping(const))

| r = <open range with operator>(<greater than or equals sign>(), const) then
  mk-Open-range(rangeOperator(r, "">=""), Mapping(const))

| <closed range>(c1, c2) then
  mk-Closed-range(mk-Open-range(rangeOperator(r, "">=""), Mapping(c1),
    mk-Open-range(rangeOperator(r, ""<=""), Mapping(c2)) )

| sc=<size constraint>(rc) then
  mk-Size-constraint(rangeOperator(sc, "length"), Mapping(rc))

```

## Auxiliary functions

The function *isDefinedSym0* is used to determine if the given symbol is defined and the each parameter's sort is the same as that of the specified syntype.

```

isDefinedSym0(sd:<syntype definition>, sym: SYMBOL0): BOOLEAN =def
  (let dtd=sd.derivedDataType0 in
    if sym ∈ { ""<"" , "">"" , ""<="", "">=""} then
      (∃ll ∈ <literal list>: ll.surroundingScopeUnit0 = dtd) ∨
      (∃os ∈ <operation signature>: (os.surroundingScopeUnit0 = dtd) ∧
        (let fpl= os.operationSignatureParameterList0 in
          os.entityName0 = sym ∧
          os.s-<result>.s-<sort>.sortId0 = predefinedId0("Boolean") ∧
          fpl.length = 2 ∧
          getEntityDefinition0(fpl[1].s-<sort>.sortId0, sort) = sd ∧
          getEntityDefinition0(fpl[2].s-<sort>.sortId0, sort) = sd
        endlet))
    else // sym ∈ { "length" }
      (∃os ∈ <operation signature>: os.surroundingScopeUnit0 = dtd ∧
        (let fpl=os.operationSignatureParameterList0 in
          os.name0 = "length" ∧
          os.s-<result>.s-<sort>.sortId0 = predefinedId0("Natural") ∧
          fpl.length = 1 ∧
          getEntityDefinition0(fpl[1].s-<sort>.sortId0, sort).derivedDataType0 = dtd
        endlet))
    endlet)

```

*rangeOperator*(rc: <range condition>, t: TOKEN): Identifier

**mk-Identifier**(

```

  endlet // decision
  endcase, // sort id
  sort).derivedDataType0.fullQualifierWithin0 // sort def - derived type – qualifier within
), // Mapping – for qualifier
mk-Name(t)

```

### F2.2.9.8.5 Synonym definition

#### Concrete syntax

```

<synonym definition> :: <synonym definition item>+
<synonym definition item> =
  <internal synonym definition item> | <external synonym definition item>
<internal synonym definition item> ::
  <synonym<name> [<sort>] <constant expression>
<external synonym definition item> ::
  <synonym<name> <predefined><sort>

```

#### Conditions on concrete syntax

The conditions below are from clause 12.1.8.3 *Concrete grammar* of [ITU-T Z.104].

$$\forall \text{syno} \in \langle \text{internal synonym definition item} \rangle: \\ \neg \text{isContainedInConsExp0}(\text{syno}, \text{syno.s-}\langle \text{constant expression} \rangle)$$

The <constant expression> shall not refer to the synonym defined by the <synonym definition> either directly or indirectly (via another synonym).

$$\forall \text{sdi} \in \langle \text{internal synonym definition item} \rangle: \text{sdi.s-}\langle \text{sort} \rangle \neq \text{undefined} \Rightarrow \\ \exists \text{s} \in \langle \text{sort} \rangle: \text{s} \in \text{sdi.s-}\langle \text{constant expression} \rangle.\text{staticSortSet0} \wedge \text{isSameSort0}(\text{s}, \text{sdi.s-}\langle \text{sort} \rangle)$$

If a <sort> is specified, the sort of the <constant expression> has to be compatible with this sort.

$\forall sdi \in \langle \text{internal synonym definition item} \rangle$ :  
 $|sdi.s-\langle \text{constant expression} \rangle.staticSortSet0| > 1 \Rightarrow sdi.s-\langle \text{sort} \rangle \neq \text{undefined}$

If the sort of the  $\langle \text{constant expression} \rangle$  is unique (that is, the expression belongs to only one sort), it is allowed to omit the  $\langle \text{sort} \rangle$  in the  $\langle \text{synonym definition} \rangle$  and the *Sort-reference-identifier* is derived from the constant expression sort.

## Transformations

$\langle \text{synonym definition} \rangle (\langle sd \rangle \hat{\ } rest)$  **provided**  $rest \neq \text{empty} \Rightarrow$   
 $\mathbf{mk}\text{-}\langle \text{synonym definition} \rangle (\langle sd \rangle) \hat{\ } \mathbf{mk}\text{-}\langle \text{synonym definition} \rangle (rest)$

A  $\langle \text{synonym definition} \rangle$  that defines multiple synonyms is a shorthand for a sequence of  $\langle \text{synonym definition} \rangle$  items, each defining one synonym. See clause 12.1.8.3 *Model* of [ITU-T Z.104].

$\langle \text{external synonym definition item} \rangle (\text{name}, \text{sort}) \Rightarrow$   
 $\mathbf{mk}\text{-}\langle \text{internal synonym definition item} \rangle (\text{name}, \text{sort}, \text{take}(\{s \in \text{sort}\}))$

An  $\langle \text{external synonym definition item} \rangle$  defines a  $\langle \text{synonym} \rangle$  whose result is not defined in a specification. See clause 12.1.8.3 *Concrete grammar* of [ITU-T Z.104].

## Mapping to abstract syntax

```
| <synonym definition>(sdi)
then
  mk-Variable-definition(Mapping(sdi.s-<name>),
    if sdi ∈ <internal synonym definition item> ∧ |sdi.s-<constant expression>.staticSortSet0|=1
    then Mapping(sdi.s-<constant expression>.staticSortSet0)
    else Mapping(sdi.s-<sort>)
    endif, // sort
    PART, // aggregation
    if sdi ∈ <internal synonym definition item>
    then Mapping(sdi.s-<constant expression>)
    else undefined
    endif // constant expression
  )
```

The paragraphs below are from clause 12.1.8.3 *Concrete grammar* of [ITU-T Z.104].

A  $\langle \text{synonym definition} \rangle$  represents a *Variable-definition* in the context in which the synonym definition appears with the special property that the variable is read-only. The  $\langle \text{synonym} \langle \text{name} \rangle$  represents the *Variable-name*.

If a  $\langle \text{sort} \rangle$  is specified, this determines the *Sort-reference-identifier* of the *Variable-definition*.

If the  $\langle \text{sort} \rangle$  in the  $\langle \text{synonym definition} \rangle$  is omitted the *Sort-reference-identifier* of the *Variable-definition* is derived from the constant expression sort.

The *Variable-definition* has a **PART** has *Aggregation-kind*.

The  $\langle \text{constant expression} \rangle$  in the concrete syntax denotes a *Constant-expression* in the abstract syntax.

## Auxiliary functions

The function *isContainedInConsExp0* is used to determine if a  $\langle \text{constant expression} \rangle$  refers to the synonym defined by the enclosing  $\langle \text{synonym definition} \rangle$  either directly or indirectly.

$isContainedInConsExp0(\text{def}: \langle \text{internal synonym definition item} \rangle, \text{exp}: \langle \text{constant expression} \rangle)$ :  
 $\text{BOOLEAN} =_{\text{def}}$   
 $\exists \text{synold} \in \langle \text{synonym} \rangle: isAncestorAS0(\text{exp}, \text{synold}) \wedge$

 $isContainedInConsExp0$

(def, getEntityDefinition0(synold, **synonym**).s-<constant expression>))

## F2.2.9.9 Use of data

### F2.2.9.9.1 Expressions and expressions as actual parameters

#### Abstract syntax

<i>Expression</i>	=	<i>Constant-expression</i>   <i>Active-expression</i>
<i>Constant-expression</i>	::	<i>Agent-instance-pid-value</i>   <i>Conditional-expression</i>   <i>Equality-expression</i>   <i>Operation-application</i>   <i>Range-check-expression</i>   <i>Type-check-expression</i>   <i>Type-coercion</i>   <i>Literal</i>
<i>Active-expression</i>	::	<i>Agent-instance-pid-value</i>   <i>Conditional-expression</i>   <i>Equality-expression</i>   <i>Operation-application</i>   <i>Range-check-expression</i>   <i>Type-check-expression</i>   <i>Type-coercion</i>   <i>Decoding-expression</i>   <i>Encoding-expression</i>   <i>Imperative-expression</i>   <i>Value-returning-call-node</i>   <i>Variable-access</i>
<i>Agent-instance-pid-value</i>	::	<i>Agent-instance*</i>
<i>Agent-instance</i>	::	<i>Agent-name Instance-number</i>
<i>Instance-number</i>	=	<i>Expression</i>
<i>Imperative-expression</i>	=	<i>Now-expression</i>   <i>Pid-expression</i>   <i>Timer-active-expression</i>   <i>Timer-remaining-duration</i>   <i>Active-agents-expression</i>   <i>Any-expression</i>   <i>State-expression</i>   <i>Signal-expression</i>   <i>Signallist-expression</i>
<i>Actual-parameters</i>	::	{ <i>Expression</i>   UNDEFINED }*

Please note that the above definition could be simplified. This can be done by omitting the difference between active expressions and constant expressions. This difference does not show up at any place, so it could be simply dropped.

#### Conditions on abstract syntax

See clause 12.2.1 *Abstract grammar* of [ITU-T Z.104].

```

∇ aipv ∈ Agent-instance-pid-value :
(aipv.s-Agent-instance-seq.head.s-Name ∈ {
  adef.s-Name:
    adef ∈ Agent-definition
  ∧ adef.parentAS1 ∈ Agent-type-definition
  ∧ adef.parentAS1.s-Agent-kind = SYSTEM
})

```

The leftmost item in the *Agent-instance* list of an *Agent-instance-pid-value* shall have an *Agent-name* that is the *Agent-name* of an *Agent-definition* directly contained by the *Agent-type-definition* for the system.

$$\forall aipv \in \text{Agent-instance-pid-value} : \text{isDirectlyContained1}(aipv.\mathbf{s-Agent-instance-seq})$$

Except the leftmost item, each other item in the list *Agent-instance* list of an *Agent-instance-pid-value* shall have an *Agent-name* that is the *Agent-name* of an *Agent-definition* directly contained by the *Agent-instance* item immediately to the left.

$$\begin{aligned} & \forall ai \in \text{Agent-instance} : \\ & ( ai.\mathbf{s-Expression.staticSort1} = \text{predefinedId1}(\text{"Natural"}) \\ & \wedge ( \text{isConstant1}(ai.\mathbf{s-Expression}) \wedge aipv \in \text{Agent-instance-pid-value} \wedge aipv.\mathbf{s-Agent-instance-seq}.last = ai \Rightarrow \\ & \quad (\exists adef \in \text{agentInstanceType1}(aipv.\mathbf{s-Agent-instance-seq}).\mathbf{s-Agent-definition-set} : \\ & \quad \quad adef.\mathbf{s-Name} = ai.\mathbf{s-Name}) \\ & \quad \wedge ( \text{computeInteger1}(ai.\mathbf{s-Expression}) \leq adef.\mathbf{s-Number-of-instances.s-Initial-number} ) \\ & ) ) \end{aligned}$$

The *Instance-number* of an *Agent-instance* in the *Agent-instance-pid-value* of a *Constant-expression* shall be a positive *Natural Constant-expression* less than or equal to the *Initial-number* of the *Number-of-instances* of the *Agent-definition* for the *Agent-name* in the same *Agent-instance*.

## Concrete syntax

```

<expression> =
    <expression0>
    | <range check expression>
    | <type coercion>

<expression0> =
    <binary expression>
    | <operand5>
    | <equality expression>
    | <create expression>
    | <value returning procedure call>
    | <decoding expression>
    | <encoding expression>
    | <agent instance pid value>

<simple expression> = <constant expression>

<actual parameters> = <actual parameter list>
<actual parameter list> = [ <actual parameter> ]+
<actual parameter> = <expression>

<constant expression> = <constant><expression0>

<binary expression> ::
    <expression> <infix operation name> <expression>

<operand5> :: [ <hyphen> | not ] <primary>

<primary> =
    <operator application>
    | <literal>
    | <expression>
    | <conditional expression>
    | <extended primary>
    | <active primary>
    | <synonym>

<active primary> = <variable access> | <imperative expression>

<expression list> = <expression>+

<imperative expression> =
    <now expression>

```

- | <pid expression>
- | <timer active expression>
- | <timer remaining duration>
- | <active agents expression>
- | <any expression>
- | <state expression>
- | <signal expression>
- | <signallist expression>

<agent instance pid value> :: [ <system<name> ] <agent instance>\*

<agent instance> :: <agent<name> [ <Natural<expression> ]

## Conditions on concrete syntax

$\forall consExp \in \langle expression0 \rangle: consExp.parentAS0 \in$   
 <alternative question>  $\cup$   
 <closed range>  $\cup$   
 <default initialization>  $\cup$   
 <exported variables of sort>  $\cup$   
 <field default initialization>  $\cup$   
 <internal synonym definition item>  $\cup$   
 <named number>  $\cup$   
 <number of instances>  $\cup$   
 <open range>  $\cup$   
 <open range with operator>  $\cup$   
 <timer default initialization>  $\cup$   
 <transition option>  $\cup$   
 <variables of sort>  
 $\Rightarrow isConstant0(consExp)$

An <expression0> that does not contain any <active primary>, or a <value returning procedure call> is a <constant expression>. In the contexts where a <constant expression> is required, there shall not exist an <active primary> or <value returning procedure call> within an <expression0>.

$\forall id \in \langle identifier \rangle: \forall expr \in \langle expression \rangle:$   
 (  $expr.parentAS0 \in$   
 <alternative question>  $\cup$   
 <named number>  $\cup$   
 <number of instances>  $\cup$   
 <transition option> )  
 $\wedge isAncestorAS0(expr, id) \wedge id.idKind0 \in \{\text{literal, operator, method}\} \Rightarrow$   
 $getEntityDefinition0(id, id.idKind0) \in PREDEFINEDDEFINITION0$

A <simple expression> shall contain only literals, and operations defined within the **package** `Predefined`, as defined in clause 14 of [ITU-T Z.104]. In the contexts where a <simple expression> is required, there shall only be identifiers for literals, operators or methods that are defined in **package** `Predefined`.

<agent instance pid value>.s-<name>  $\neq undefined \Rightarrow$   
 <agent instance pid value>.s-<name> =  $take(\{s \in Sdl-specification\}).s-Agent-definition.s-Name$

If a <name> is given in an <agent instance pid value>, it shall be the name of the system.

## Transformations

<binary expression>(x, <implies sign>, y)  
 =8=> **mk**-<operator application>(mk-<operator identifier>(undefined, ""=>""), <x, y>)

<binary expression>(x, **or**, y)  
 =8=> **mk**-<operator application>(mk-<operator identifier>(undefined, ""or""), <x, y>)

<binary expression>(x, **xor**, y)  
 =8=> **mk**-<operator application>(mk-<operator identifier>(undefined, ""xor""), <x, y>)

<binary expression>(x, **and**, y)  
=8=> **mk**-<operator application>(mk-<operator identifier>(undefined, ""and""), <x, y>)

<binary expression>(x, <greater than sign>, y)  
=8=> **mk**-<operator application>(mk-<operator identifier>(undefined, "">""), <x, y>)

<binary expression>(x, <greater than or equals sign>, y)  
=8=> **mk**-<operator application>(mk-<operator identifier>(undefined, "">="" ), <x, y>)

<binary expression>(x, <less than sign>, y)  
=8=> **mk**-<operator application>(mk-<operator identifier>(undefined, ""<""), <x, y>)

<binary expression>(x, <less than or equals sign>, y)  
=8=> **mk**-<operator application>(mk-<operator identifier>(undefined, ""<="" ), <x, y>)

<binary expression>(x, **in**, y)  
=8=> **mk**-<operator application>(mk-<operator identifier>(undefined, ""in""), <x, y>)

<binary expression>(x, <plus sign>, y)  
=8=> **mk**-<operator application>(mk-<operator identifier>(undefined, ""+""), <x, y>)

<binary expression>(x, <hyphen>, y)  
=8=> **mk**-<operator application>(mk-<operator identifier>(undefined, ""-""), <x, y>)

<binary expression>(x, <concatenation sign>, y)  
=8=> **mk**-<operator application>(mk-<operator identifier>(undefined, ""//""), <x, y>)

<binary expression>(x, <asterisk>, y)  
=8=> **mk**-<operator application>(mk-<operator identifier>(undefined, ""\*""), <x, y>)

<binary expression>(x, <solidus>, y)  
=8=> **mk**-<operator application>(mk-<operator identifier>(undefined, ""/""), <x, y>)

<binary expression>(x, **mod**, y)  
=8=> **mk**-<operator application>(mk-<operator identifier>(undefined, ""mod""), <x, y>)

<binary expression>(x, **rem**, y)  
=8=> **mk**-<operator application>(mk-<operator identifier>(undefined, ""rem""), <x, y>)

<operand5>(<hyphen>, x)  
=8=> **mk**-<operator application>(mk-<operator identifier>(undefined, ""-""), <x>)

<operand5>(not, x)  
=8=> **mk**-<operator application>(mk-<operator identifier>(undefined, ""not""), <x>)

NOTE 1 – The qualifier binding of the <operator identifier> items is undefined in the transformations, and is determined by the context of the <binary expression>/<operand5> and/or the sorts of the parameters x and y.

An expression of the form

<expression> <infix operation name> <expression>

is derived syntax for

<quotation mark> <infix operation name> <quotation mark> (<expression>, <expression>)

where <quotation mark> <infix operation name> <quotation mark> represents an Operation-name.

Similarly,

<monadic operation name> <expression>

is derived syntax for

<quotation mark> <monadic operation name> <quotation mark> (<expression> )

where <quotation mark> <monadic operation name> <quotation mark> represents an Operation-name.

## Mapping to abstract syntax

```
| <agent instance piv value>(*, ailst)
then
mk-Agent-instance-pid-value(
  mk-Agent-instance(
    take({adef.s-Name:
      adef ∈ Agent-definition
    ^ adef.parentASI ∈ Agent-type-definition
    ^ adef.parentASI.s-Agent-kind = SYSTEM
    })),
    predefinedLiteral1 ("Natural", "1") // agent instance for system
  ) ^
  <Mapping(ailst[i]): i ∈ 1.. ailst.length > // rest of agent instances
) //Agent-instance-pid-value
```

The keyword **system** in <agent instance pid value> represents the first item of the *Agent-instance* list of the *Agent-instance-pid-value* with the *Name* for the system and an *Instance-number* for the `Natural` number "1". See clause 12.2.1 of [ITU-T Z.104].

```
| <agent instance>(nm, expr)
then
mk-Agent-instance(Mapping(nm),
  if expr = undefined then predefinedLiteral1("Natural", "1") else Mapping(expr) endif
)
```

If the <Natural<expression> of an <agent instance pid value> is omitted, this represents the `Natural` number "1". See clause 12.2.1 of [ITU-T Z.104].

NOTE 2 – Clause 12.2.1 of [ITU-T Z.104] also includes the following text: "If the <Natural<expression> value of an <agent instance pid value> is zero or greater than the number of active instances of the agent instance set, the <agent instance pid value> represents the `Pid value Null`" that is evaluated in the Dynamic Semantics (even if it is a constant expression, which could be evaluated here).

## Auxiliary functions

The function *isConstant0* is used to determine whether an <expression0> is a <constant expression>.

```
isConstant0(expr: <expression0>): BOOLEAN =def
  ¬∃activePri ∈ <active primary>: isAncestorAS0(expr, activePri) ∧
  ¬∃vrpc ∈ <value returning procedure call>: isAncestorAS0(expr, vrpc)
```

The function *isConstant1* is used to determine whether an *Expression* is a *Constant-expression*.

```
isConstant1(expr: Expression): BOOLEAN =def
  ¬∃impExpr ∈ Imperative-expression: isAncestorAS1(expr, impExpr) ∧
  ¬∃var ∈ Variable-access: isAncestorAS1(expr, var) ∧
  ¬∃vrpc Value-returning-call-node: isAncestorAS0(expr, vrpc)
```

The function *isDirectlyContained1* is used to determine that the elements of an agent instance list are directly contained so that each item is contained within items to the left.

```
isDirectlyContained1(alst: Agent-instance*): BOOLEAN =def
if alst.length < 2 then true
else
  isDirectlyContained1(substring(alst,1,length-1))
  ^
  ( ∃! atdef ∈ Agent-type-definition:
    ( ∃ adef ∈ atdef.s-Agent-definition-set:
      ( adef.s-Name = alst[length].s-Name )
    )
  )
endif
```

The function *agentInstanceType1* is used to determine the *Agent-type-definition* of the right most instance of a *Agent-instance list*.

```

agentInstanceType1(alst: Agent-instance*): Agent-type-definition =def
if alst.length < 2 then take({st ∈ Agent-type-definition : st.s-Agent-kind = SYSTEM })
else
  take({atdef ∈ Agent-type-definition:
    atdef.Identifier1 = adef.s-Identifier // id of type def is given by agent def, agent type id
    ∧ adef.s-Name = alst[length].s-Name // name of agent def is last item name of Agent instance list
    ∧ // agent def is a member of the Agent def set defined for the agent instance to the left
      adef ∈ agentInstanceType1(substring(alst,1,length-1)).s-Agent-definition-set
  })
endif

```

### F2.2.9.9.2 Literal

See clause 12.2.2 *Concrete grammar* of [ITU-T Z.101].

#### Abstract syntax

*Literal* :: *Literal-identifier*

#### Concrete syntax

<literal> = <literal identifier>  
 <literal identifier> :: [ <qualifier> ] <literal name>

#### Conditions on concrete syntax

$\forall litId \in \langle \text{literal identifier} \rangle : (litId.s-\langle \text{qualifier} \rangle = \text{undefined} \Rightarrow$   
 $(|\text{staticSortSet0}(\langle \text{operand5} \rangle(\text{undefined}, litId))| = 1))$

It shall be possible to bind each unqualified <literal identifier> to exactly one sort that satisfies the conditions in the construct in which the <literal identifier> is used. See clause 12.2.2 *Concrete grammar* of [ITU-T Z.101].

#### Mapping to abstract syntax

```

| litId = <literal identifier>(qual, name) then
mk-Identifier(
  Mapping(qual), // full qualifiers resolved before mapping
  uniqueLiteralName0(name,
    if qual.s-<path item>-seq.last.s1 = type
    then mk-<identifier>(
      <pi[i]: ∈ 1..qual.s-<path item>-seq.length-1 > // qualifier
      qual.s-<path item>-seq.last.s-<name>
    ) // sort id
    else take(staticSortSet0(mk-<operand5>(undefined, litId))) // sort from context
    endif // unique name
  )
) // Identifier

```

For the following two paragraphs, see clause 12.2.2 *Concrete grammar* of [ITU-T Z.101].

Whenever a <literal identifier> is specified, the unique *Literal-name* in *Literal-identifier* is derived in the same way, with the result sort derived from context. A *Literal-identifier* is derived from context (see clause 6.2) so that if the <literal identifier> is overloaded (that is, the same name is used for more than one literal or operation), then the *Literal-name* identifies a visible literal with the same name and result sort consistent with the literal. If there are two literals with the same <name> but differing by result sorts, each has a different *Literal-name*.

Wherever a <qualifier> of a <literal identifier> ends with a <path item> with the keyword **type**, then the <sort name> is used as the result sort to derive the unique *Name* of the *Identifier*. The *Qualifier*

is formed in the usual way from <qualifier>, therefore the <sort name> after the keyword **type** is used for both the *Qualifier* and deriving the *Name* of the *Identifier*.

### F2.2.9.9.3 Synonym

#### Concrete syntax

<synonym> :: <synonym><identifier>

#### Mapping to abstract syntax

| <synonym>(ident) then **mk-Variable-access**(**mk-Variable-identifier**(Mapping(ident)))

A <synonym> represents the *Variable-identifier* for the identified synonym identifier. See clause 12.2.8 *Concrete grammar* of [ITU-T Z.104].

### F2.2.9.9.4 Extended primary

#### Concrete syntax

<extended primary> =  
     <indexed primary>  
     | <field primary>  
     | <composite primary>

<indexed primary> :: <primary> <actual parameter list>

<field primary> :: [<primary>] { <field name> | <field number> | <as signal> }

<field name> = <name>

<field number> = <Natural><name>

<composite primary> :: <qualifier> <actual parameter list>

#### Conditions on concrete syntax

$\forall fp \in \langle \text{field primary} \rangle$ :  
 ( $fp.s\text{-primary} = \text{undefined} \Rightarrow fp.s\text{-implicit} \in \langle \text{field name} \rangle$ )

The condition is needed because AS0 is simplified with respect to clause 12.2.3 *Concrete grammar* of [ITU-T Z.104] where <primary> is only optional when a <field name> is given.

#### Transformations

<indexed primary>(prim, params)  
 =8=> **mk-Method-application**(prim, **mk-Identifier**(empty, "Extract"), params)

An <indexed primary> is derived concrete syntax for

Extract (<primary>, <actual parameter list>)

See clause 12.2.3 *Model* of [ITU-T Z.101]. The abstract syntax is determined from this concrete expression according to clause 12.2.1 of [ITU-T Z.101].

<field primary>(prim, field)  
**provided** prim  $\neq$  undefined  $\wedge$  field  $\notin$  (<field number>  $\cup$  <as signal> )  
 =8=> **mk-Method-application**(prim, **modifyExtractName**(field, "Extract"), empty)

A <field primary> is derived concrete syntax for

*field-extract-name*(<primary> )

where the *field-extract-name* is formed from the concatenation of the field name and "Extract" in that order. The abstract syntax is determined from this concrete expression according to clause 12.2.1 of [ITU-T Z.101]. See clause 12.2.3 *Model* of [ITU-T Z.101]. The transformation according to this model is performed before the modification of the signature of methods in clause 12.1.3 of [ITU-T Z.104].

```

<field primary>(prim, fieldnum)
provided prim ≠ undefined ∧ fieldnum ∈ <field number>
=8=>
let td = mk-<operand5>(undefined, prim).staticSort0.refersto0 in // type definition
mk-<field primary>(prim,
  fieldNameList0( // list of field names for the data type definition
    if td ∈ <data type definition> then td
    else td.parentDataType0 // td is syntype definition, get the parent data type
    endif.s-<data type definition body>.s-implicit
  )[intTokenToNat(fieldnum)] // field number selects field name from field name list
) // revised field primary
endlet // td

```

A <field number> is a shorthand for the <field name> of a field of the sort of <field primary> or <field variable>, where the value 1 represents the first field, the value 2 the second field and the value n the nth field. See clause 12.2.3 *Model* of [ITU-T Z.104].

```

<field primary>(prim, asSig)
provided prim ≠ undefined ∧ asSig ∈ <as signal>
=8=>
<field primary>(prim, asSig.s-<identifier>.asSignal.s-<name>)

```

An <as signal> in a <field primary> is a shorthand for the <field name> of a field of the sort of the <field primary>, where the <field name> is the same as the unique anonymous name of the structure data type defined by the <signal definition> identified by the <signal identifier> of <as signal>. See clause 12.2.3 *Model* of [ITU-T Z.104].

```

<field primary>(undefined, field)
=8=> mk-<field primary>(mk-<variable access>(this), field)

```

When the <field primary> has the form <field name>, this is derived syntax for:

**this** ! <field name>

See clause 12.2.3 *Model* of [ITU-T Z.104].

```

<composite primary>(qual, params)
=8=>
mk-<operator application>( mk-<identifier>(qual, "Make"), params)

```

A <composite primary> is derived concrete syntax for:

<qualifier> Make ( <actual parameter list> )

if any actual parameters were present, or

<qualifier> Make

otherwise, and where the <qualifier> is inserted only if it was present in the <composite primary>. See clause 12.2.3 *Model* of [ITU-T Z.101]. The abstract syntax is determined from this concrete expression according to clause 12.2.1 of [ITU-T Z.101].

### F2.2.9.9.5 Equality expression

#### Abstract syntax

<i>Equality-expression</i>	=	<i>Positive-equality-expression</i>   <i>Negative-equality-expression</i>
<i>Positive-equality-expression</i>	::	<i>First-operand</i> <i>Second-operand</i>
<i>Negative-equality-expression</i>	::	<i>First-operand</i> <i>Second-operand</i>
<i>First-operand</i>	=	<i>Expression</i>
<i>Second-operand</i>	=	<i>Expression</i>

## Concrete syntax

<equality expression> ::  
    <expression> { <equals sign> | <not equals sign> } <expression>

## Conditions on concrete syntax

$\forall ee \in \langle \text{equality expression} \rangle$ :  
    **let** *set1* = *ee*.**s**-<expression>.staticSortSet0 **in**  
    **let** *set2* = *ee*.**s2**-<expression>.staticSortSet0 **in**  
         $\exists s1 \in \textit{set1} : \exists s2 \in \textit{set2} : \textit{isSortCompatible0}(s1, s2) \vee \textit{isSortCompatible0}(s2, s1)$   
    **endlet**

An <equality expression> is legal concrete syntax only if the sort of one of its operand is sort compatible to the sort of the other operand.

## Mapping to abstract syntax

| <equality expression>(first, <equals sign>, second) **then**  
    **mk-Positive-equality-expression**(Mapping(first), Mapping(second))  
  
| <equality expression>(first, <not equals sign>, second) **then**  
    **mk-Negative-equality-expression**(Mapping(first), Mapping(second))

## F2.2.9.9.6 Conditional expression

### Abstract syntax

*Conditional-expression*                    ::     *Boolean-expression*  
  *Consequence-expression*  
  *Alternative-expression*  
  
*Consequence-expression*                =     *Expression*  
*Alternative-expression*                 =     *Expression*

### Conditions on abstract syntax

$\forall c \in \textit{Conditional-expression}$ :  
     $(c.\textit{s-Consequence-expression.staticSort1} = c.\textit{s-Alternative-expression.staticSort1}) \wedge$   
     $(c.\textit{s-Boolean-expression.staticSort1} = \textit{predefinedId1}(\text{"Boolean"}))$

For any *Conditional-expression*, the sort of the *Consequence-expression* shall be the same as that of the *Alternative-expression*. See clause 12.2.5 *Abstract grammar* of [ITU-T Z.101].

## Concrete syntax

<conditional expression> ::  
    <Boolean-expression> <consequence expression> <alternative expression>  
  
<consequence expression> = <expression>  
  
<alternative expression> = <expression>

## Mapping to abstract syntax

| <conditional expression>(e1, e2, e3) **then**  
    **mk-Conditional-expression**(Mapping(e1), Mapping(e2), Mapping(e3))

## F2.2.9.9.7 Operation application

### Abstract syntax

*Operation-application*                    ::     *Operation-identifier* *Actual-parameters*

### Conditions on abstract syntax

$\forall oa \in \textit{Operation-application}$ :  
    **let** *os* = *getEntityDefinition1*(*oa*, **operation**) **in**

*isActualAndFormalParameterMatched1*(*oa.s-Expression-seq*, *os.formalParameterSortList1*)  
**endlet**

Each *Expression* in the list of *Expression* of the *Actual-parameters* of the *Operation-application* shall be sort compatible to the corresponding (by position) sort in the list of *Formal-argument* list of the *Operation-signature*. There shall be no **UNDEFINED** elements in the *Actual-parameters* of the *Operation-application*. See clause 12.2.6 *Abstract grammar* of [ITU-T Z.101].

### Concrete syntax

<operation application> = <operator application> | <method application>  
 <operator application> :: <operation identifier> [ <actual parameters> ]  
 <method application> :: <primary> <operation identifier> [ <actual parameters> ]

### Conditions on concrete syntax

$\forall methodApp \in \langle \text{method application} \rangle$ :  
 $getEntityDefinition0(methodApp.s-\langle \text{identifier} \rangle, \mathbf{method}) \neq \text{undefined}$

A <method application> is legal concrete syntax only if <operation identifier> represents a method. See clause 12.2.6 *Concrete syntax* of [ITU-T Z.104].

### Transformations

$\langle \text{method application} \rangle(\text{prim}, \text{ident}, \text{params}) =_8 \Rightarrow$   
 $\langle \text{operator application} \rangle(\text{ident}, \langle \text{prim} \rangle \hat{\ } \text{params})$

The concrete syntax form

<expression> <full stop> <operation identifier> [<actual parameters>]

is derived concrete syntax for

<operation identifier> new-actual-parameters

where new-actual-parameters is <actual parameters> containing only <expression>, if <actual parameters> was not present; otherwise new-actual-parameters is obtained by inserting <expression> before the first optional expression in <actual parameters>. See clause 12.2.6 *Model* of [ITU-T Z.104].

### Mapping to abstract syntax

$\langle \text{operator application} \rangle(\text{ident}, \text{params}) \mathbf{then}$   
 $\mathbf{mk-Operation-application}(Mapping(\text{ident}), Mapping(\text{params}))$

### Auxiliary functions

Get the actual parameter list associated with the *Operation-identifier*.

*actualParameterListOfOpId1*(*id: Operation-identifier*): [*Expression*]\* =<sub>def</sub>  
**case** *id.parentAS1* **of**  
 | *Open-range* **then** <*id.parentAS1.s-Constant-expression*>  
 | *Operation-application* **then** < *exp* | *exp* **in** *id.parentAS1.s-Expression-seq*>  
**endcase**

### F2.2.9.9.8 Range check expression

#### Abstract syntax

*Type-check-expression* :: *Expression Parent-sort-identifier*  
*Range-check-expression* :: *Expression Parent-sort-identifier Range-condition*

#### Conditions on abstract syntax

$\forall rce \in \text{Range-check-expression}$ :

- ( *isCompatibleTo1*(*rce.s-Expression.staticSort1*, *rce.s-Parent-sort-identifier*) )
- ∨ ( *getEntityDefinition1*(*rce.s-Parent-sort-identifier*, **interface**) ≠ *undefined*
- ∧ *isCompatibleTo1*(*rce.s-Expression.staticSort1*, *Mapping*(*predefinedId0*("Pid"))))

The sort of the *Expression* of a *Range-check-expression* shall be sort compatible with the sort identified by the *Parent-sort-identifier*, or the sort *Pid* if the *Parent-sort-identifier* is a *pid* sort. See clause 12.1.7 *Abstract grammar* [ITU-T Z.101].

## Concrete syntax

```
<range check expression> ::
    <expression>
    { <range check constrained sort> | <syntype> | <pid sort> | <datatype<type expression> }

<range check constrained sort> :: <sort<identifier> <constraint>
```

## Conditions on concrete syntax

- ∀ *rccs* ∈ <range check constrained sort>:
  - rccs.s-<identifier>.fullIdentifier0* ≠ *predefinedId0*("Pid")
  - ∨ *getEntityDefinition0*(*rccs.s-<identifier>*, **interface**) ≠ *undefined*

The <sort<identifier> of a <range check constrained sort> shall not be *Pid* or a *pid* sort. See clause 12.1.7 *Concrete grammar* [ITU-T Z.101].

## Mapping to abstract syntax

```
| <range check expression>(expr, srt) then
case srt of
| <range check constrained sort> then
    mk-Range-check-expression(
        Mapping(expr),
        Mapping(srt.s-<identifier>),
        Mapping(srt.s-<constraint>)
    )
| <syntype> then
    mk-Range-check-expression(
        Mapping(expr),
        Mapping(srt),
        Mapping(srt.refersto0.s-implicit.s-<constraint>)
    )
| <pid sort> then
    mk-Range-check-expression(
        Mapping(expr),
        Mapping(srt),
        mk-Range-check-expression(∅)
    )
| <datatype<type expression> then
    mk-Type-check-expression(
        Mapping(expr),
        Mapping(srt),
    )
endcase // srt
```

The <expression> represents the *Expression*. If the form <range check constrained sort> is used, the <sort<identifier> represents the *Parent-sort-identifier* that applies to the <constraint>, which represents the *Range-condition* as described in clause 12.1.8.2. If the <sort<identifier> in <range check constrained sort> identifies a syntype, this is the same as specifying the parent sort identifier of the syntype, and the <constraint> is not restricted to the range of the syntype. If the form <syntype> is used, *Parent-sort-identifier* and *Range-condition* are the *Parent-sort-identifier* and *Range-condition* (respectively) of the identified syntype. If the form <pid sort> is used, it determines the *Parent-sort-identifier* and the *Range-condition* is empty. See clause 12.1.7 *Concrete grammar* [ITU-T Z.101] (with <operand2> replaced by <expression>).

If the form  $\langle \text{datatype} \langle \text{type expression} \rangle$  is used, the  $\langle \text{range check expression} \rangle$  represents a *Type-check-expression*. The  $\langle \text{expression} \rangle$  represents the *Expression*. The  $\langle \text{datatype type expression} \rangle$  determines the *Parent-sort-identifier*. See clause 12.1.7 *Concrete grammar* [ITU-T Z.107] (with  $\langle \text{operand2} \rangle$  replaced by  $\langle \text{expression} \rangle$ )

### F2.2.9.9.9 Variable definition

#### Abstract syntax

*Variable-definition* :: *Variable-name*  
*Sort-reference-identifier*  
*Aggregation-kind*  
[ *Constant-expression* ]

*Aggregation-kind* = PART | REF

#### Conditions on abstract syntax

$\forall d \in \text{Variable-definition}: d.s\text{-Constant-expression} \neq \text{undefined} \Rightarrow$   
 $d.s\text{-Constant-expression}. \text{staticSort1} = d.s\text{-Sort-reference-identifier}$

If the *Constant-expression* is present, it shall be sort compatible with the *Sort-reference-identifier* denoted. See clause 12.3.1 *Abstract grammar* of [ITU-T Z.101].

#### Concrete syntax

$\langle \text{variable definition} \rangle :: \langle \text{variables of sort} \rangle + | \langle \text{exported variables of sort} \rangle +$   
 $\langle \text{variables of sort} \rangle ::$   
 $\langle \text{aggregation kind} \rangle \langle \text{variable} \langle \text{name} \rangle + \langle \text{sort} \rangle [ \langle \text{constant expression} \rangle ]$   
 $\langle \text{exported variables of sort} \rangle ::$   
 $\langle \text{aggregation kind} \rangle \langle \text{exported variable} \rangle + \langle \text{sort} \rangle [ \langle \text{constant expression} \rangle ]$   
 $\langle \text{exported variable} \rangle :: \langle \text{variable} \langle \text{name} \rangle \langle \text{remote variable} \langle \text{identifier} \rangle$   
 $\langle \text{aggregation kind} \rangle :: [ \text{part} | \text{ref} ]$

#### Conditions on concrete syntax

$\forall d \in \langle \text{agent definition} \rangle \cup \langle \text{agent type definition} \rangle:$   
 $\neg(\exists v1, v2 \in \langle \text{exported variable} \rangle: v1 \neq v2 \wedge v1.s\text{-} \langle \text{identifier} \rangle = v2.s\text{-} \langle \text{identifier} \rangle \wedge$   
 $v1.\text{parentAS0}.\text{parentAS0} \in \langle \text{variable definition} \rangle \wedge$   
 $v2.\text{parentAS0}.\text{parentAS0} \in \langle \text{variable definition} \rangle \wedge$   
 $v1.\text{surroundingScopeUnit0} = d \wedge v2.\text{surroundingScopeUnit0} = d)$

Two exported variables in an agent shall not mention the same  $\langle \text{remote variable identifier} \rangle$ . See clause 12.3.1 *Abstract grammar* of [ITU-T Z.102].

#### Transformations

$\langle \text{variables of sort} \rangle (ak, varList, sort, expr)$  **provided**  $varList.length > 1$   
 $=5 \Rightarrow$   
**mk-** $\langle \text{variables of sort} \rangle (ak, \langle varList.head \rangle, sort, expr) \wedge$   
**if**  $varList.length > 1$  **then** **mk-** $\langle \text{variables of sort} \rangle (ak, varList.tail, sort, expr)$  **else empty endif**

A  $\langle \text{variables of sort} \rangle$  that defines multiple variables is a shorthand for a sequence of  $\langle \text{variables of sort} \rangle$  items, each defining one variable.

$\langle \text{exported variables of sort} \rangle (ak, evarList, sort, expr)$  **provided**  $evarList.length > 1$   
 $=5 \Rightarrow$   
**mk-** $\langle \text{exported variables of sort} \rangle (ak, \langle evarList.head \rangle, sort, expr) \wedge$   
**if**  $evarList.length > 1$  **then** **mk-** $\langle \text{exported variables of sort} \rangle (ak, evarList.tail, sort, expr)$  **else empty endif**

An  $\langle \text{exported variables of sort} \rangle$  that defines multiple variables is a shorthand for a sequence of  $\langle \text{exported variables of sort} \rangle$  items, each defining one variable.

```

<variable definition> (varDefList) provided varDefList.length > 1
=5=>
mk-<variable definition> (< varDefList head >) ^
if varDefList.length > 1 then mk-<variable definition> (ak, varDefList t.tail, sort, expr) else empty endif

```

A <variable definition> that defines multiple <variables of sort> or <exported variables of sort> items is a shorthand for a sequence of <variable definition>s, each defining one item. Combined with the transforms for <variables of sort> and <exported variables of sort>, the consequence is each <variable definition> defines one variable.

## Mapping to abstract syntax

```

| <variable definition>(*, < var >) then Mapping(var)

| <variables of sort>(ak, <name>, sort, const) then
  mk-Variable-definition(Mapping(name),
    Mapping(sort),
    Mapping(ak),
    Mapping(
      if const = undefined then getEntityDefinition0(sort, sort).getDefaultInitialization0 else const endif
    )
  )

```

If no initialization is given in <variables of sort>, "if the data type that defined the <sort> has a <default initialization>, then the <constant expression> of the <default initialization>" (See item (b) in clause 12.3.1 *Concrete grammar* of [ITU-T Z.101]) is used for the initialization.

```

| <exported variables of sort>(ak, < ev >, sort, const) then
  mk-Variable-definition(
    Mapping(ev.s-<name>),
    Mapping(sort),
    Mapping(ak), Mapping(
      if const = undefined then getEntityDefinition0(sort, sort).getDefaultInitialization0 else const endif
    )
  )

| <aggregation kind>(ak) then
  case ak of
  | undefined then PART
  | part then PART
  | ref then REF
  endcase

```

### F2.2.9.9.10 Variable access

#### Abstract syntax

Variable-access :: Variable-identifier

#### Concrete syntax

<variable access> :: { <variable><identifier> | **this** | <import expression> }

#### Conditions on concrete syntax

```

∀ va ∈ <variable access>: va.s-implicit = this ⇒
  (parentASOfKind(va, <operation definition>) ≠ undefined ∧
  parentASOfKind(va, <operation definition>).kind0=method) // before transformation to a procedure
∨ (∃ od ∈ <operation definition> :
  od.operatorProcedureId ≠ undefined ∧ od.kind0=method
  ∧ od.operatorProcedureId.refersto0 = parentASOfKind(va, <internal procedure definition >)
  ) // after method body transformed into an anonymous procedure

```

**this** shall only occur in method definitions. See clause 12.3.2 *Concrete grammar* of [ITU-T Z.104].

## Transformations

```
va = <variable access>(this)
provided parentASOfKind(va, <internal procedure definition >) ≠ undefined // anon proc for method
=8=>
mk-<variable access>(parentASOfKind(va, <internal procedure definition >).s-<procedure heading>.
s-<formal variable parameters>.head.s-<parameters of sort>.s-<name>.head)
```

A <variable access> using the keyword **this** is replaced by the anonymous name introduced as the name of the leading parameter in <arguments> according to clause 12.1.3 *Model* of [ITU-T Z.104]. See clause 12.3.2 *Model* of [ITU-T Z.104].

## Mapping to abstract syntax

```
| <variable access>(identifier) then mk-Variable-access(mk-Variable-identifier(Mapping(identifier)))
```

### F2.2.9.9.11 Assignment

#### Abstract syntax

```
Assignment :: Variable-identifier Expression
```

#### Conditions on abstract syntax

```
∀a ∈ Assignment: ∃d ∈ (Variable-definition ∪ Parameter):
(d=getEntityDefinition1(a.s-Variable-identifier, variable)) ∧
isCompatibleTo1(a.s-Expression.staticSort1, d.s-Sort-reference-identifier)
```

In an *Assignment*, the sort of the *Expression* shall be sort compatible to the sort of the *Variable-identifier*. See clause 12.3.3 *Abstract grammar* of [ITU-T Z.101].

```
∀a ∈ Assignment:
let d = getEntityDefinition1(a.s-Variable-identifier, variable) in // d is a Variable-definition or Parameter
let ex = a.s-Expression in
  (if d ∈ Variable-definition
   then d.s-Aggregation-kind
   else d.s-Parameter-aggregation.s-Aggregation-kind
  endif = REF)
⇒
( (ex ∈ Variable-access)
 ∧ ( getEntityDefinition1(ex.s-Variable-identifier, variable).s-Aggregation-kind = PART // variable
   ∨ getEntityDefinition1(ex.s-Variable-identifier, variable).s-Parameter.s-Aggregation-kind
     = PART // parameter
   ) // variable access for Variable-definition or Parameter
 ) // Expression is a variable access = variable identifier
∨
( (ex ∈ Operation-application) // struct/choice ops have PART return aggregations
 ∧ (isSpecialStructOp1(ex.s-Operation-identifier) ∨ isSpecialChoiceOp1(ex.s-Operation-identifier))
 )
endlet // ex
endlet // d
```

```
∀a ∈ Assignment:
let d = getEntityDefinition1(a.s-Variable-identifier, variable) in //d is a Variable-definition or Parameter
let ex = a.s-Expression in
  ((if d ∈ Variable-definition
   then d.s-Aggregation-kind
   else d.s-Parameter-aggregation.s-Aggregation-kind
  endif = PART)
 ⇒
  ( (ex ∉ Literal)
   ∨ (ex ∈ Literal ∧ ex.s-Literal.s-Name.s-TOKEN ≠ ""null"")
  )
endlet // ex
```

**endlet // d**

If the *Variable-identifier* refers to a *Variable-definition* with *Aggregation-kind* **REF** and the *Expression* has aggregation kind **PART**, the *Expression* shall be a *Variable-identifier* or an *Operation-application* which accesses a field of a data type defined in a <structure definition> or <choice definition>. If the *Variable-identifier* refers to a *Variable-definition* with *Aggregation-kind* **PART**, the *Expression* shall not be the *Null-literal-signature*. See clause 12.3.3 Assignment, Abstract grammar, of [ITU-T Z.107].

### Concrete syntax

<assignment> :: <variable> <expression>  
<variable> = <variable-identifier> | <extended variable>

### Mapping to abstract syntax

| <assignment>(var,expr) then **mk-Assignment**(var,expr)

### F2.2.9.9.12 Extended variable

#### Concrete syntax

<extended variable> = <indexed variable> | <field variable>  
<indexed variable> :: <variable> <actual parameter list>  
<field variable> :: <variable> { <field name> | <field number> | <as signal> }

#### Transformations

<assignment>( <indexed variable>(var, params), expr)  
=8=>  
**mk-assignment**(var, **mk-method application**(var, **mk-identifier**(empty, "Modify"), expr))

<indexed variable> is derived concrete syntax for

<variable> <is assigned sign> <variable> <full stop> **Modify** ( expressionlist )

where expressionlist is constructed by appending <expression> to the <actual parameter list>. The abstract grammar is determined from this concrete expression according to clause 12.2.1 of [ITU-T Z.101]. The same model applies to the second form of <indexed variable>.

<assignment>( <field variable>(var, fieldname), expr)  
=8=>  
**mk-assignment**(var, **mk-method application**(var, **modifyExtractName**(fieldname, "Modify"), expr))

The concrete syntax form

<variable> <exclamation mark> <field name> <is assigned sign> <expression>

is derived concrete syntax for

<variable> <full stop> field-modify-operation-name ( <expression> )

where the field-modify-operation-name is formed from the concatenation of the field name and "Modify". The abstract syntax is determined from this concrete expression according to clause 12.2.1 of [ITU-T Z.101]. The same model applies to the second form of <field variable>.

#### Auxiliary functions

**modifyExtractName**(name: <identifier>, suffix: *TOKEN*):<identifier> =<sub>def</sub>  
**mk-identifier**(name.s-<qualifier>, name.s-<name> + suffix)

### F2.2.9.9.13 Default initialization

#### Abstract syntax

*Default-initialization* = *Constant-expression*

#### Concrete syntax

<default initialization> :: [<virtuality>] [<constant expression>]

#### Conditions on concrete syntax

$\forall \text{init} \in \langle \text{default initialization} \rangle$ :  
 $\text{init.s} \langle \text{constant expression} \rangle = \text{undefined} \Rightarrow \text{init.virtuality} \in \{\text{redefined, finalized}\}$

The <constant expression> shall only be omitted if <virtuality> is **redefined** or **finalized**. See clause 12.2.1 *Concrete grammar* of [ITU-T Z.104].

#### Auxiliary functions

The function *getDefaultInitialization0* computes the default initialization for a data type or syntype.

```
getDefaultInitialization0(type: <data type definition>  $\cup$  <syntype definition>): <default initialization> =def  
  case type of  
  | <data type definition> then  
    let tb = type.s <data type definition body> in  
    if tb  $\neq$  undefined then  
      let di = tb.s <default initialization> in  
      if di  $\neq$  undefined then  
        if di.s <constant expression>  $\neq$  undefined then di else undefined endif  
      else  
        type.s <data type specialization>.s <base type>.seq.baseInitialization0  
      endif  
    endlet // di  
  else type.s <parent sort identifier>.getDefaultInitialization0  
  endif  
  endlet // tb  
  | <syntype definition> then  
    let sds = type.s <syntype definition syntype> in  
    let di = sds.s <default initialization> in  
    if di  $\neq$  undefined then di  
    else sds.s <parent sort identifier>.getDefaultInitialization0  
    endif  
    endlet // di  
  endlet // sds  
  endcase
```

The function *baseInitialization0* returns the <default initialization> for the first <base type> (in the list of a <data type specialization>) that has a <default initialization> or *undefined* if there is no <default initialization>.

```
baseInitialization0(bl: <base type>*): <default initialization> =def  
  if bl  $\neq$  undefined  
  then  
    let di = bl.head.getDefaultInitialization0 in  
    if di  $\neq$  undefined then di  
    else  
      let blt = bl.tail in  
      if blt.length  $\neq$  0 then blt.baseInitialization0 else undefined endif  
      endlet // blt  
    endif  
  endlet // di  
  else undefined  
  endif
```

### F2.2.9.9.14 Now expression

#### Abstract syntax

*Now-expression* :: ()

#### Concrete syntax

<now expression> :: ()

#### Mapping to abstract syntax

| <now expression> then mk-*Now-expression*()

### F2.2.9.9.15 Import expression

#### Concrete syntax

<import expression> :: <remote variable><identifier> <communication constraints>

#### Conditions on concrete syntax

$\forall exp \in \langle \text{import expression} \rangle: exp.s\text{-}\langle \text{identifier} \rangle \in$   
(let  $d = \text{parentASofKind}(exp, \langle \text{agent definition} \rangle \cup \langle \text{agent type definition} \rangle)$  in  
 $exp.s\text{-}\langle \text{identifier} \rangle \in d.\text{validOutputSignalSet0}$   
endlet)

A remote variable mentioned in an <import expression> shall be in the complete output set of an enclosing agent type or agent set. See clause 10.6 *Concrete grammar* of [ITU-T Z.102].

NOTE 1 – The <destination> in the <communication constraints> of an <import expression> has to be compatible with the remote variable, which is described in more detail in clause F2.2.7.6, Remote variable.

#### Transformations

The import expression has implied syntax for the importing of the result as defined in clause 10.6 of [ITU-T Z.102] and it also has an implied Variable-access of the implied variable for the import in the context where the <import expression> appears. See clause 12.3.4.5 *Model* of [ITU-T Z.104].

NOTE 2 – The transformation of <import expression> is described in clause F2.2.7.6, Remote variable.

### F2.2.9.9.16 Pid expression

#### Abstract syntax

*Pid-expression* =  
| *Self-expression*  
| *Parent-expression*  
| *Offspring-expression*  
| *Sender-expression*

*Self-expression* :: ()

*Parent-expression* :: ()

*Offspring-expression* :: ()

*Sender-expression* :: ()

#### Concrete syntax

<pid expression> =  
| <self expression>  
| <parent expression>  
| <offspring expression>  
| <sender expression>

<self expression> :: ()

<parent expression> :: ()

<offspring expression> :: ()

<sender expression> :: ()  
 <create expression> = <create body>

## Transformations

The use of <create expression> in an expression is a shorthand for inserting a create request just before the action where the <create expression> occurs followed by an assignment of offspring to an implicitly declared anonymous variable of the same sort as the static sort of the <create expression>. The implicit variable is then used in the expression. If <create expression> occurs several times in an expression, one distinct variable is used for each occurrence. In this case the order of the inserted create requests and variable assignments is the same as the order of the <create expression>s.

If the <create expression> contains an <agent type identifier> then the transformations that are applied to a create statement that contains an <agent type identifier> are also applied to the implicit create statements resulting from the transformation of a <create expression> (see clause 11.13.2 of [ITU-T Z.103]).

## Mapping to abstract syntax

| <self expression> **then** **mk-Self-expression()**  
 | <parent expression> **then** **mk-Parent-expression()**  
 | <offspring expression> **then** **mk-Offspring-expression()**  
 | <sender expression> **then** **mk-Sender-expression()**

### F2.2.9.9.17 Timer active expression and timer remaining duration

#### Abstract syntax

*Timer-active-expression* :: *Timer-identifier Expression\**  
*Timer-remaining-duration* :: *Timer-identifier Expression\**

#### Conditions on abstract syntax

$\forall t \in \textit{Timer-active-expression} \cup \textit{Timer-remaining-duration}$ :  
**let**  $d = \textit{getEntityDefinition1}(t.s\textit{-Timer-identifier}, \textit{timer})$  **in**  
 $t.s\textit{-Expression.length} = d.s\textit{-Sort-reference-identifier.length} \wedge$   
 $(\forall i \in 1.. t.s\textit{-Expression.length}$ :  
 $\textit{isCompatibleTo1}(t.s\textit{-Expression}[i].\textit{staticSort1}, d.s\textit{-Sort-reference-identifier}[i]))$   
**endlet**

The sorts of the *Expression* list in the *Timer-active-expression* or *Timer-remaining-duration* shall correspond by position to the *Sort-reference-identifier* list directly following the *Timer-name* identified by the *Timer-identifier*.

#### Concrete syntax

<timer active expression> :: <timer<identifier> [ <expression list> ]  
 <timer remaining duration> :: <timer<identifier> [ <expression list> ]

#### Mapping to abstract syntax

| <timer active expression>(id,l) **then**  
**mk-Timer-active-expression**(Mapping(id), Mapping(l))  
 | <timer remaining duration>(id,l) **then**  
**mk-Timer-remaining-duration**(Mapping(id), Mapping(l))

### F2.2.9.9.18 Active agents expression

#### Abstract syntax

*Active-agents-expression* :: { *Agent-identifier* | **THIS** }

## Concrete syntax

<active agents expression> :: { <agent<identifier> | **this** }

## Conditions on abstract syntax

$\forall exp \in \langle \text{create body} \rangle: (exp.s\text{-implicit} = \mathbf{this}) \Rightarrow$   
 $(exp.surroundingScopeUnit0 \in \langle \text{agent type definition} \rangle) \wedge$   
 $(exp.surroundingScopeUnit0.surroundingScopeUnit0 \in \langle \text{agent type definition} \rangle)$

**this** shall only be specified in an <agent type diagram> and in scopes enclosed by an <agent type diagram> and represents **THIS**.

## Mapping to abstract syntax

| <active agents expression>(id=<identifier>) **then** *mk-Active-agents-expression*(Mapping(id))

| <active agents expression>( **this** ) **then** *mk-Active-agents-expression*(**THIS**)

### F2.2.9.9.19 Any expression

#### Abstract syntax

*Any-expression* :: *Sort-reference-identifier*

#### Concrete syntax

<any expression> :: <sort>

#### Mapping to abstract syntax

| <any expression>(s) **then** *mk-Any-expression*(Mapping(s))

### F2.2.9.9.20 State expression

#### Abstract syntax

*State-expression* :: ()

#### Concrete syntax

<state expression> :: ()

#### Mapping to abstract syntax

| <state expression>() **then** *mk-State-expression*

### F2.2.9.9.21 Signal expression

#### Abstract syntax

*Signal-expression* :: ()

#### Concrete syntax

<signal expression> :: ()

#### Mapping to abstract syntax

| <signal expression>() **then** *mk-Signal-expression*

### F2.2.9.9.22 Signallist expression

#### Abstract syntax

*Signallist-expression* :: ()

## Concrete syntax

<signallist expression> ::()

## Mapping to abstract syntax

| <signallist expression>() **then** *mk-Signallist-expression*

### F2.2.9.9.23 Value returning procedure call

#### Abstract syntax

*Value-returning-call-node* :: [ **THIS** ]  
*Procedure-identifier*  
*Actual-parameters*

#### Concrete syntax

<value returning procedure call> =  
    <procedure call body>  
| <remote procedure call body>

#### Conditions on concrete syntax

$\forall exp \in \langle \text{continuous expression} \rangle: exp.parentAS0 \in \langle \text{continuous signal} \rangle \Rightarrow$   
 $\neg \exists procCall \in \langle \text{value returning procedure call} \rangle: isAncestorAS0(exp, procCall)$   
 $\forall exp \in \langle \text{provided expression} \rangle: exp.parentAS0 \in \langle \text{input part} \rangle \Rightarrow$   
 $\neg \exists procCall \in \langle \text{value returning procedure call} \rangle: isAncestorAS0(exp, procCall)$

A <value returning procedure call> shall not occur in the <Boolean expression> of a <continuous signal> or <enabling condition>. See clause 12.3.5 *Concrete grammar* of [ITU-T Z.104].

$\forall procId \in \langle \text{identifier} \rangle: procId.parentAS0 \in \langle \text{value returning procedure call} \rangle \Rightarrow$   
 $getEntityDefinition0(procId, \mathbf{procedure}).s-\langle \text{procedure heading} \rangle.s-\langle \text{procedure result} \rangle \neq \text{undefined}$

The <procedure identifier> in a <value returning procedure call> shall identify a procedure having a <procedure result>. See clause 12.3.5 *Concrete grammar* of [ITU-T Z.101].

$\forall procCall \in \langle \text{procedure call body} \rangle:$   
 $procCall \in \langle \text{value returning procedure call} \rangle \wedge procCall.s-\mathbf{this} \neq \text{undefined} \Rightarrow$   
 $getEntityDefinition0(procId, \mathbf{procedure}) =$   
 $parentAS0ofKind(procCall, \langle \text{procedure definition} \rangle)$

If **this** is used, <procedure identifier> shall denote an enclosing procedure. See clause 12.3.5 *Concrete grammar* of [ITU-T Z.104].

#### Transformations

NOTE - When the <procedure identifier> is not defined within the enclosing agent, the procedure call is transformed into a call of a local, implicitly created, subtype of the procedure as described in clause 11.13.3 *Model* of [ITU-T Z.101] and formalized in the transformation of <procedure call body> in clause F2.2.8.13.3.

## Mapping to abstract syntax

| <value returning procedure call>(<procedure call body>(t, id, params)) **then**  
*mk-Value-returning-call-node*(*Mapping*(t), *Mapping*(id), *Mapping*(params))

### F2.2.9.9.24 Type coercion

#### Abstract syntax

*Type-coercion* :: *Expression Sort-reference-identifier*

## Conditions on abstract syntax

The static sort of *Expression* shall be the sort identified by *Sort-reference-identifier*, or a parent sort of that sort. See clause 12.2.9 *Abstract grammar* of [ITU-T Z.107].

$\forall t \in \text{Type-coercion}:\text{isCompatibleTo1}(\text{staticSort1}(t.\text{s-Expression}), t.\text{s-Sort-reference-identifier})$

## Concrete syntax

$\langle \text{type coercion} \rangle :: \langle \text{expression} \rangle \langle \text{sort} \rangle$

## Mapping to abstract syntax

$|\langle \text{type coercion} \rangle(e, s) \text{ then } \text{mk-Type-coercion}(\text{Mapping}(e), \text{Mapping}(s))$

### F2.2.10 Computing constants

This clause contains auxiliary functions used to compute values for constants.

#### Auxiliary functions

*value1* returns a member of *VALUE1* (a *Literal-signature*).

```
value1(e: Constant-expression):VALUE1 =def
  case e of
  | Literal(lid) then computeLiteral1(lid)
  | Conditional-expression(bool, consequence, alternative) then
    if bool.value1.semvalueBool1 then consequence.value1 else alternative.value1 endif
  | Positive-equality-expression(a, b) then computeEquality1(a.value1, b.value1)
  | Negative-equality-expression(a, b) then computeInEquality1(a.value1, b.value1)
  | Operation-application(op, values) then computeConstant1(op, < v.value1: v in values >)
  | Range-check-expression(range, expr) then expr.value1 ∈ range.range1
  | Type-check-expression(expr, parent) then
    isCompatibleTo1(getEntityDefinition1(expr.value1.s-Result.s-Sort-reference-identifier, sort),
    getEntityDefinition1(parent.s-Result.s-Sort-reference-identifier, sort))
  | Type-coercion(expr, *) then expr.value1
  | Agent-instance-pid-value(ail) then computeAgentPid1(ail)
  endcase
```

*computeLiteral1* returns the *Literal-signature* corresponding to the literal.

```
computeLiteral1(id: Literal-identifier): VALUE1 =def
  getEntityDefinition1(id, idKind1(id)).s-Literal-signature
```

*semvalueBool1* returns the *BOOLEAN* value true if the *Literal-signature* is the Boolean value true, otherwise it returns the *BOOLEAN* value false.

```
semvalueBool1(b: Literal-signature): BOOLEAN =def
  if b= mk-Literal-signature(mk-Name("true"), mk-Result(predefinedId1("Boolean"),
  mk-Result-aggregation(PART)), 0)
  then true else false endif // Nat value for true is 0, Nat value for false is 1
```

*computeEquality1* returns the Boolean *Literal-signature* for true if the value of both expressions is the same, and the Boolean *Literal-signature* for false otherwise.

```
computeEquality1(a: Literal-signature, b: Literal-signature): Literal-signature =def
  mk-Literal-signature (
  if a = b then mk-Name("true") else mk-Name("false") endif,
  mk-Result(predefinedId1("Boolean"), mk-Result-aggregation(PART)),
  if a = b then 0 else 1 endif)
```

*computeInEquality1* returns the Boolean *Literal-signature* for false if the value of *computeEquality1* is the Boolean *Literal-signature* for true, and the Boolean *Literal-signature* for true otherwise.

```
computeInEquality1(a: Literal-signature, b: Literal-signature): Literal-signature =def
```

```

let eq = computeEqualityI (a, b).s-Name.s-TOKEN = "true" in
mk-Literal-signature (
  if eq then mk-Name("false") else mk-Name("true") endif,
  mk-Result(predefinedIdI("Boolean"), mk-Result-aggregation(PART)),
  if eq then 1 else 0 endif)
endlet

```

*computeConstantI* returns the *Literal-signature* for the value of applying the operation to the constant expression argument values for the operation. The name of the data type is derived from the *Operation-identifier*: the operation is defined within a data type; therefore the last *Path-item* of the *Qualifier* of the *Operation-identifier* is the *Data-type-name* of this data type. If the part of the *Qualifier* of the *Operation-identifier* before the *Data-type-name* is the **package** Predefined, the data type is one of the predefined data types there is selection of the appropriate compute function.

```

computeConstantI(op: Operation-identifier, values: VALUEI*): Literal-signature =def
if op.s-Qualifier.length = 2
  ^ op.s-Qualifier.head ∈ Package-qualifier
  ^ op.s-Qualifier.head.s-Package-name = "Predefined"

endif

```

*computeInteger1* returns (to *computeConstant1*) the *Literal-signature* for the value of applying the Integer operation to the Integer constant expression argument values. There are no integer literals for negative integers in the concrete grammar: instead negative values are represented by the application of the unary minus operation. However, in the formal model *Literal-signature* items are defined for negative values with the integer *Name* preceded by a "-". The *Literal-natural* value for an integer for positive integers is twice the integer value. For a negative integer n the *Literal-natural* value is -2\*n-1.

```

```

Each positive Real is actually a positive rational number that can be written as a/b where a and b are natural numbers such that there is no common divisor between a and b, and these are counted. The sequence function *S* that is used for the counting maps all of the natural numbers to all of the positive rational numbers and is:

$$S(0) = 0$$

$$S(1) = 1$$

$$S(2n) = S(n) + 1 \text{ for all } n > 0$$

$$S(2n + 1) = 1/S(2n) \text{ for all } n > 0$$

In the following incomplete table, where the rational is given before the = sign and the number after the sign is the count. The shaded cells with an X, each denotes a rational that has the same value as one already counted: for example, 8/6 and 4/3. The count is doubled for the literal natural value, so that if the count for positive real *r* is *n* its literal natural is the even number 2\**n* and the literal natural for  $-r$  is the odd number 2\**n*-1.

Dividend/ Divisor	1	2	3	4	5	6	7	8
1	1/1 = 1	1/2 = 3	1/3 = 5	1/4 = 9	1/5 = 17	1/6 = 33	1/7 = 65	1/8 = 129
2	2/1 = 2	2/2 = X	2/3 = 7	2/4 = X	2/5 = 13	2/6 = X	2/7 = 25	2/8 = X
3	3/1 = 4	3/2 = 6	3/3 = X	3/4 = 11	3/5 = 15	3/6 = X	3/7 = 21	3/8 = 29
4	4/1 = 8	4/2 = X	4/3 = 10	4/4 = X	4/5 = 19	4/6 = X	4/7 = 23	4/8 = X
5	5/1 = 16	5/2 = 12	5/3 = 14	5/4 = 18	5/5 = X	5/6 = 35	5/7 = 27	5/8 = 31
6	6/1 = 32	6/2 = X	6/3 = X	6/4 = X	6/5 = 34	6/6 = X	6/7 = 67	6/8 = X
7	7/1 = 64	7/2 = 24	7/3 = 20	7/4 = 22	7/5 = 26	7/6 = 66	7/7 = X	7/8 = 131
8	8/1 = 128	8/2 = X	8/3 = 28	8/4 = X	8/5 = 30	8/6 = X	8/7 = 130	8/8 = X

The inverse function  $S^{-1}$  that gives a natural for the rational  $p/q$  is:

$$S^{-1}(0/q) = 0$$

$$S^{-1}(p/p) = 1$$

$$S^{-1}(p/1) = 2^{p-1} \text{ for } p > 1$$

$$S^{-1}(p/q) = 2 \times S^{-1}((p/q) - 1) \text{ for } p > q$$

$$S^{-1}(p/q) = S^{-1}(q/p) + 1 \text{ for } p < q$$

The *RATIONAL* domain represents each rational number where the *RATIONAL* is represented by (0,1) or the greatest common divisor between the two natural numbers is 1. All cases where the dividend is zero are the same (zero) value. All cases where there is a common divisor are equivalent to the value where the dividend and divisor are divided by their greatest common divisor. Negative values are denoted by the application of the unary minus function.

$$RATIONAL =_{\text{def}} r \in \{ NAT \times NAT : (r.s1-NAT = 0 \Rightarrow (r.s2-NAT = 0)) \\ \vee (r.s1-NAT > 0 \wedge r.s2-NAT > 0 \wedge gcd(r.s1-NAT, r.s2-NAT) = 1) \}$$

The *rational2Nat* function is  $S^{-1}$  in ASM notation.

```

rational2Nat(r: RATIONAL): NAT =def
let p = r.s1-NAT in
let q = r.s2-NAT in
if p = 0 then 0
elseif p = q then 1
elseif q = 1 then 2*rational2Nat(p-1, 1)
elseif p > q then 2*rational2Nat(p-q, q)
else rational2Nat(q, p) + 1 // p < q
endif
endlet // q
endlet // p

```

The inverse function is *nat2Rational*.

```

nat2Rational(n: NAT): RATIONAL =def
if n = 0 then mk-RATIONAL(0, 0)
elseif n = 1 then mk-RATIONAL(1, 1)
elseif ( $\exists i \in NAT$ ) (i > 1  $\wedge$  2(i-1) = n) then mk-RATIONAL(i, 1)
else take( $\{ r \in RATIONAL : \text{rational2Nat}(r) = n \}$ )
endif

```

The *Literal-natural* value for a positive real *r* is twice the *rational2Nat*(*r*) value. The *Literal-natural* value for a negative real, *r* is 2\**rational2Nat*(-*r*) - 1.

The *computeRealI* function returns (to *computeConstantI*) the *Literal-signature* for the value of applying the Real operation to the constant expression argument values.

```

computeRealI(op: Operation-identifier, values: VALUEI*): Literal-signature =def

```

```

The function *makeTimeLitSig1* returns the time *Literal-signature* for the rational (p/q) where p and q are naturals.

```

makeTimeLitSig1(p, q: NAT) : Literal-signature =def
mk-Literal-signature(
  mk-Name(natToIntToken(p / gcd(p,q)) + "/" + natToIntToken(q / gcd(p,q))), // literal name
  mk-Result(predefinedId1("Time"), mk-Result-aggregation(PART)), // Result is Time
  2*rational2Nat(mk-RATIONAL(p / gcd(p,q), q / gcd(p,q))), // literal natural
) // Literal-signature

```

The rest of this clause gives the signature of a number of auxiliary functions that are not currently formally specified for reasons of economy of effort. The functions to compute the literal signatures when computing constants during the analysis should be derived from the definition of the relevant data type in [ITU-T Z.104] in a similar way to the compute functions for the data types given above.

*computeBit1* returns (to *computeConstant1*) the *Literal-signature* for the value of applying the Bit operation to the constant expression argument values.

```

computeBit1(op: Operation-identifier, values: VALUE1*): Literal-signature =def
// The body of this function is not currently specified formally.

```

*computeBitstring1* returns (to *computeConstant1*) the *Literal-signature* for the value of applying the Bitstring operation to the constant expression argument values.

```

computeBitstring1(op: Operation-identifier, values: VALUE1*): Literal-signature =def
// The body of this function is not currently specified formally.

```

*computeOctetstring1* returns (to *computeConstant1*) the *Literal-signature* for the value of applying the Octetstring operation to the constant expression argument values.

```

computeOctetstring1(op: Operation-identifier, values: VALUE1*): Literal-signature =def
// The body of this function is not currently specified formally.

```

*computePid1* returns (to *computeConstant1*) the *Literal-signature* for the value of applying the Pid operation to the constant expression argument values.

```

computePid1(op: Operation-identifier, values: VALUE1*): Literal-signature =def
// The body of this function is not currently specified formally

```

*computeTeletexChar1* returns (to *computeConstant1*) the *Literal-signature* for the value of applying the TeletexChar operation to the constant expression argument values.

```

computeTeletexChar1(op: Operation-identifier, values: VALUE1*): Literal-signature =def

```

// The body of this function is not currently specified formally.

*computeTeletexString1* returns (to *computeConstant1*) the *Literal-signature* for the value of applying the TeletexString operation to the constant expression argument values.

*computeTeletexString1*(*op*: Operation-identifier, values: VALUE1\*): *Literal-signature* =<sub>def</sub>  
// The body of this function is not currently specified formally.

*computeVideotexChar1* returns (to *computeConstant1*) the *Literal-signature* for the value of applying the VideotexChar operation to the constant expression argument values.

*computeVideotexChar1*(*op*: Operation-identifier, values: VALUE1\*): *Literal-signature* =<sub>def</sub>  
// The body of this function is not currently specified formally.

*computeVideotexString1* returns (to *computeConstant1*) the *Literal-signature* for the value of applying the VideotexString operation to the constant expression argument values.

*computeVideotexString1*(*op*: Operation-identifier, values: VALUE1\*): *Literal-signature* =<sub>def</sub>  
// The body of this function is not currently specified formally.

*computeUniversalChar1* returns (to *computeConstant1*) the *Literal-signature* for the value of applying the UniversalChar operation to the constant expression argument values.

*computeUniversalChar1*(*op*: Operation-identifier, values: VALUE1\*): *Literal-signature* =<sub>def</sub>  
// The body of this function is not currently specified formally.

*computeUniversalString1* returns (to *computeConstant1*) the *Literal-signature* for the value of applying the UniversalString operation to the constant expression argument values.

*computeUniversalString1*(*op*: Operation-identifier, values: VALUE1\*): *Literal-signature* =<sub>def</sub>  
// The body of this function is not currently specified formally.

*isSpecialLiteralOp1* determines if the operator is one of the implicit literal operators (num, "<", ">", "<=", ">=", first, last, succ, pred) of a data type created from a literals list constructor (that is, with a non-empty *Literal-signature-set*).

*isSpecialLiteralOp1*( *op* : Operation-identifier ): *BOOLEAN* =<sub>def</sub>  
// The body of this function is not currently specified formally.

*computeLiteralOp1* returns (to *computeConstant1*) the *Literal-signature* for the value of applying the special literal operation (see *isSpecialLiteralOp1*) to the constant expression argument values.

*computeLiteralOp1*( *op* : Operation-identifier, values: VALUE1\*): *Literal-signature* =<sub>def</sub>  
// The body of this function is not currently specified formally.

*isSpecialStructOp1* determines if the operator is one of the operators (Make, fnExtract, fnModify, fnPresent, undefined) of a data type created from a structure definition, which is distinguished from a choice definition by the presence of parameters to Make, and the absence of PresentExtract.

*isSpecialStructOp1*( *op* : Operation-identifier ): *BOOLEAN* =<sub>def</sub>  
// The body of this function is not currently specified formally.

*computeStructOp1* returns (to *computeConstant1*) the *Literal-signature* for the value of applying the special struct operation (see *isSpecialStructOp1*) to the constant expression argument values.

*computeStructOp1*( *op* : Operation-identifier, values: VALUE1\*): *Literal-signature* =<sub>def</sub>  
// The body of this function is not currently specified formally.

*isSpecialChoiceOp1* determines if the operator is one of the operators (Make, fn, fnExtract, fnModify, fnPresent, PresentExtract, undefined) of a data type created from a choice definition.

*isSpecialChoiceOp1*( *op* : Operation-identifier ): *BOOLEAN* =<sub>def</sub>  
// The body of this function is not currently specified formally.

*computeChoiceOp1* returns (to *computeConstant1*) the *Literal-signature* for the value of applying the special choice operation (see *isSpecialChoiceOp1*) to the constant expression argument values.

```
computeChoiceOp1( op : Operation-identifier, values: VALUE1*): Literal-signature =def  
// The body of this function is not currently specified formally.
```

*computeAgentPid1* returns (to *computeConstant1*) the `Pid` value identified by the *Agent-instance* list.

```
computeAgentPid1(ail: Agent-instance*): Literal-signature =def  
// The body of this function is not currently specified formally.
```

### F2.3 Transformation of SDL-2010 shorthands

This clause details the transformation of the SDL-2010 constructs, whose dynamic semantics are given after a transformation to the subset of SDL-2010 for which *Abstract Grammar* exists. These shorthand notations are constructs for which a *Model* section exists.

The properties of a shorthand notation are derived from the way it is modelled in terms of (or transformed to) the primitive concepts. In order to ensure easy and unambiguous use of the shorthand notations, and to reduce side effects when several shorthand notations are combined, these concepts are transformed in a specified order as detailed in this clause.

The specified order of transformation means that in the result of the transformation of a shorthand notation of order *m*, another shorthand notation of order *n* may be used, provided  $n > m$ . The order of the transformation is given as a number inside the transformation arrow, e.g.,  $=5=>$  for a transformation of order 5.

The transformations are described as a number of enumerated steps. One step may describe the transformation of several concepts and thus consist of a number of sub-steps, either because these concepts must be transformed as a group or because the transformation order between these concepts is not significant.

If entities are moved to different scopes during the subsequent transformation steps, the `<qualifier>`s in every `<identifier>` bound to such an entity are updated to reflect this change. In fact, this case should not happen in the new version of SDL-2010.

The following enumeration details the transformation steps to be performed in order.

- 1) Lexical transformations:
  - a) `<macro definition>` items and `<macro call>` items (see clause 6.7 of [ITU-T Z.102]) are identified lexically and `<macro call>` items are expanded;
  - b) `<macro definition>` items are removed (also in `<package definition>` items).
    - These transformations are not described formally, i.e., no macros are considered in the formal semantics.
    - This step also includes simple transformations (such as removal of separators) that just adapt the AS0.
- 2) operations are handled, **public** removed from `<operation signature>` and `<literal signature>` items:
  - omitted parameter kind replaced by **in**. See clause 9.4 *Model* of [ITU-T Z.103];
  - the `<operation signature>` of each method is transformed to an `<operation signature>` of the equivalent operator. See clause 12.1.3 of [ITU-T Z.104];
  - `<operation definition>` items are transformed into procedures having anonymous names and having the result as `<procedure result>`. See clause 12.1.7 of [ITU-T Z.101] and clause 12.1.7 of [ITU-T Z.104].
  - `<inline data type definition>` (see clause 12.1 of [ITU-T Z.104]);

- <inline syntype definition> (see clause 12.1 of [ITU-T Z.104]);
  - remove **public** (see clause 12.1.9 of [ITU-T Z.104]).
- 3) <task> items and <statements> lists are transformed as defined in clause 11.13.1 of [ITU-T Z.103], clause 11.14 of [ITU-T Z.102] and clause 11.14 of [ITU-T Z.103].
- 4) Definition references are replaced by <referenced definition>s (see clause 7.3 of [ITU-T Z.101]).
- 5) The graphs are normalized, name lists are expanded to one name per item, omitted items with defaults set to the default:
- non-terminating decisions and non-terminating transition options are transformed into terminating decisions and terminating transition options respectively (clause 5.7.12.5 of [ITU-T Z.106]);
  - the actions and/or terminator statement following the decisions and transition options are moved to appear as <free action>s. Those generated <free action>s which have no label attached are given anonymous labels;
  - action lists (including the terminator statement which follows) where the first action (if any, otherwise the following terminator statement) has a label attached, are replaced by a join to the label and the action list appears as a <free action>;
  - a system specification that is a process or block is replaced by a system enclosing the process or block as in clause 7.1 of [ITU-T Z.103];
  - each <signal definition list> that has multiple <signal definition> items is replaced by multiple <signal definition list> items each containing one <signal definition> as described in clause 10.3 of [ITU-T Z.101];
  - each <signal definition> has a (usually anonymous) name defined for the associated data type as in clause 10.3 of [ITU-T Z.104];
  - each <variables of sort>/<exported variables of sort> that has multiple <name>/<exported variable> (respectively) items is replaced by multiple <variables of sort>/<exported variables of sort> (respectively) items each containing one <name>/<exported variable> (respectively), and each <variable definition> that has multiple <variables of sort>/<exported variables of sort> items is replaced by multiple <variable definition> items each containing one <variables of sort>/<exported variables of sort>, so that each replacement <variable definition> defines one variable;
  - each <fields of sort> that has multiple <field of kind> items is replaced by multiple <fields of sort> items each containing one <field<name>, so that each <field> contains only one <field<name> (clause 12.1.6.2 of [ITU-T Z.104]);
  - each <synonym definition> that has more than one <synonym definition item> is replaced by multiple <synonym definition> items each containing one <internal synonym definition item>/<external synonym definition item>;
  - the local variables of compound and loop statements are expanded so that each <variable definition statement> defines one variable (clause 11.14.1 of [ITU-T Z.102]);
  - multiple timer set/reset clauses in a <set>/<set statement>/<reset>/<reset statement> are replaced by multiple <set>/<set statement>/<reset>/<reset statement> items each containing one set/reset clause, and multiple timer definition items in a timer definition are replaced by multiple timer definitions (clause 11.15 of [ITU-T Z.103]);
  - formal variable parameters have omitted parameter kind items set to **in** (clause 9.5 of [ITU-T Z.103]);
  - procedure formal parameters are expanded so that each <formal variable parameters> defines the name of only one parameter (derived from clause 8.1.1.1 of [ITU-T Z.101]);

- add unique implicit connector name for a compound statement without a <connector name> (clause 11.14.1 of [ITU-T Z.102]);
  - add unique implicit names for unnamed channels (clause 10.1 [ITU-T Z.103]).
- 6) Package use is transformed:
- the package Predefined is included in the <sdl specification> as in clause 7.1 of [ITU-T Z.101];
  - if the same <package<identifier> occurs in multiple <package use clause> items associated with a definition, these <package use clause> items are replaced by a single <package use clause> for that <package<identifier> as in clause 7.2 *Model* of [ITU-T Z.101].
- 7) Transformation of:
- generic system (see clause 13 of [ITU-T Z.102]) and external data (an <external synonym definition item> – see clause 12.1.8.3 of [ITU-T Z.104], an operation defined by an <external operation definition> – see clause 12.1.7 of [ITU-T Z.104], a procedure defined by an <external procedure definition> – see clause 9.4 of [ITU-T Z.103], or <informal text> in a transition option);
  - identifiers in <simple expression> items contained in the <sdl specification> are bound to definitions. During this binding, only <data definition> items defined in the predefined package Predefined and <external synonym definition> items are considered (that is, all other <data definition> items are ignored);
  - <simple expression> items are evaluated and <select definition> items <transition option> items are replaced by the selected items.
- 8) Transformation of:
- <synonym> to a <constant expression> (see clause 12.1 of [ITU-T Z.104]);
  - <basic sort> with a <range condition> (see clause 12.1 of [ITU-T Z.104]);
  - non-deterministic decision (see clause 11.13.5 of [ITU-T Z.102]);
  - operations involving <infix operation name>s and their operands transformed to the prefix form (see clause 12.2.1 of [ITU-T Z.104]);
  - for every <operation definition> which does not have a corresponding <operation signature>, construct an <operation signature>: see clause 12.1.7 of [ITU-T Z.104];
  - structure data type (<structure definition>: see clause 12.1.6.2 of [ITU-T Z.101] and clause 12.1.6.2 of [ITU-T Z.104]);
  - state list (<state list>: see clause 11.2 of [ITU-T Z.103]);
  - more than one <stimulus> or asterisk in an <input list> (see clause 11.3 of [ITU-T Z.103]);
  - more than one <priority stimulus> or asterisk in an <priority input> (see clause 11.4 of [ITU-T Z.103]);
  - more than one <save item> or asterisk in a <save list> (see clause 11.7 of [ITU-T Z.103]);
  - more than one <state exit point> or asterisk in a <connect list> of a <connect part> (see clause 11.11.4 of [ITU-T Z.103]);
  - field primary (see clause 12.2.3 of [ITU-T Z.101] and clause 12.2.3 of [ITU-T Z.104]);
  - composite primary (for structure or array values: or clause 12.2.3 of [ITU-T Z.101]);
  - the range constraint for <syntype definition>s (see clause 12.1.8.2 of [ITU-T Z.101]);
  - multiple signals and multiple destinations in <output body> (see clause 11.13.4 of [ITU-T Z.103]);

- multiple timers in <set body> and <reset body> (see clause 11.15 of [ITU-T Z.103]);
  - channel to channel connections replacing them with gates on the (implicit) agent type (see clause 10.2 of [ITU-T Z.103]);
  - default duration value for timer set (see clause 11.15 of [ITU-T Z.101]);
  - initialization of variables of sorts with default initialization (see clause 12.3.1 of [ITU-T Z.101], clause 12.3.3.2 of [ITU-T Z.101] and clause 12.3.3.2 of [ITU-T Z.104]);
  - <stimulus> containing <indexed variable>s and <field variable>s are transformed (see clause 11.3 of [ITU-T Z.103]);
  - replacing signallist definitions by interface definitions (see clause 12.1.2 Model of [ITU-T Z.103]);
  - replacing interface gate definitions by gate definitions (see clause 8.1.4 Model of [ITU-T Z.103]);
  - replacing interface identifiers from interface definitions by a list of signal identifiers (see clause 10.4 Semantics of [ITU-T Z.101]);
  - indexed primary (see clause 12.2.3 of [ITU-T Z.101] and clause 12.2.3 of [ITU-T Z.104]);
  - field variable (see clause 12.3.3.1 of [ITU-T Z.101]);
  - indexed variable (see clause 12.3.3.1 of [ITU-T Z.101]);
  - <return body> with <expression> (see clause 11.12.2.4 of [ITU-T Z.101]);
  - <procedure call body> that calls a procedure defined outside the agent type, transformed into a call of an implicitly defined local procedure (see clause 11.13.3 of [ITU-T Z.101]);
  - <value returning procedure call> containing a <procedure call body> so that an implicit procedure is added (see clause 11.13.3 of [ITU-T Z.101]);
  - implicit name for state timer with an expression (rather than a set clause);
  - implicitly named parameterless timer definition for state timer with an expression;
  - anonymous names for choice data types defined by gate definitions for use by <as gate> (see clause 8.1.4 of [ITU-T Z.104]);
  - empty parameters of Make (see clause 12.1.6.2 of [ITU-T Z.101]);
  - <field number> of <field primary> to a <field name> (see clause 12.2.3 of [ITU-T Z.104]);
  - <as signal> of <field primary> to a <field name> (see clause 12.2.3 of [ITU-T Z.104]);
  - <syntype definition data type> (see clause 12.1.8.1 of [ITU-T Z.104]);
  - insert the unique path for an omitted <encoding path> in <encoding expression> or <decoding expression> (see clause 10.7 of [ITU-T Z.104]);
- 9) Insertion of implicit channels as described in clause 10.1 of [ITU-T Z.103].
- 10) Insertion of implicit signal lists as described in clauses 10.5 and 10.6 of [ITU-T Z.102].
- 11) Handle context parameters, specialize data types and generate anonymous names
- expand list context parameters so that only one name in each list (clauses 8.3.5 to 8.3.9 and 8.3.13 of [ITU-T Z.102]);
  - replacement of context parameters described in clause 8.1.2 of [ITU-T Z.102] and clause 8.3 of [ITU-T Z.102];
  - specialize data types as described in clause 8.4 of [ITU-T Z.102] augmented by clause 12.1.9 of [ITU-T Z.104];
  - allocate anonymous type name for type expressions as in clause 8.1.2 of [ITU-T Z.102];

- allocate anonymous names for procedures that represent operations as in clause 12.1.7 of [ITU-T Z.101];
  - allocate anonymous names for unnamed default start and unnamed return of composite state types for default entry and exits clause 11.11.2 of [ITU-T Z.102].
- 12) Transformation of shorthand notations <agent definition>, <agent body> and <composite state definition>:
- each <agent definition> into an <agent type definition> and a <textual typebased agent definition> as described in clause 9 of [ITU-T Z.103];
  - each <agent body> of an <agent type definition> into a <composite state type definition> and a <textual typebased composite state> as described in clause 8.1.1.1 of [ITU-T Z.103];
  - each <composite state definition> into a <composite state type definition> and a <typebased composite state> as described in clauses 9, 9.5 and 11.2 of [ITU-T Z.103];
  - each <via path> in a resulting <composite state type definition> that is a <channel identifier> into a <gate identifier> as described 11.3 of [ITU-T Z.103];
  - each <encoding path> that refers to a channel is transformed to refer to an encoding path that refers to a gate as described in clause 10.7 of [ITU-T Z.104].
- 13) Derivation of signal list for any channel path with omitted signal list:
- If an associated <signal list> is omitted from a <channel definition>, the <signal list> is replaced by a <signal list> derived from the channel connection (see clause 10.1 of [ITU-T Z.103]).
- 14) Full qualifiers are inserted:
- According to the visibility rules and the rules for resolution by context (see clause 6.6 of [ITU-T Z.101]), qualifiers are extended to denote the full path. This binding takes into account specialization such as: the replacement of an <anchored sort> by the <basic sort> of the **parent** base type or **this** local subsort (see clauses 12.1 and 12.1.9 of [ITU-T Z.104]).
- 15) Transformation of asterisk state:
- A body originating from an agent definition or procedure definition has its asterisk states expanded according to the model defined in clause 11.2 of [ITU-T Z.103].
  - Multiple appearance of state is merged (see clause 11.2 of [ITU-T Z.103]).
- 16) Transformation of global block variables:
- A block with a global variable definition (a <variable definition> as an <entity in agent> in the <agent structure> of the block/system type of the block/system) has a state machine that is interpreted concurrently with agents in the block/system. Access from contained agents in the block/system to a global variable of the block is covered by two implicitly defined remote procedures for setting and getting the data item associated with the variable. See clause 9.2 of [ITU-T Z.102].
- 17) Implicit declarations for remote procedures and remote variables (see clauses 10.5 and 10.6 of [ITU-T Z.102]) are generated. Imported and exported values (see clause 10.6 of [ITU-T Z.102])) are transformed. Then remote procedures (see clause 10.5 of [ITU-T Z.102])) are transformed.

NOTE – Text in [ITU-T Z.101], [ITU-T Z.102], [ITU-T Z.103] and [ITU-T Z.104] referenced above describes SDL-GR, therefore needs modifying for the equivalent SDL-PR and AS0 (for example: <agent diagram> becomes <agent definition>).

## SERIES OF ITU-T RECOMMENDATIONS

Series A	Organization of the work of ITU-T
Series D	Tariff and accounting principles and international telecommunication/ICT economic and policy issues
Series E	Overall network operation, telephone service, service operation and human factors
Series F	Non-telephone telecommunication services
Series G	Transmission systems and media, digital systems and networks
Series H	Audiovisual and multimedia systems
Series I	Integrated services digital network
Series J	Cable networks and transmission of television, sound programme and other multimedia signals
Series K	Protection against interference
Series L	Environment and ICTs, climate change, e-waste, energy efficiency; construction, installation and protection of cables and other elements of outside plant
Series M	Telecommunication management, including TMN and network maintenance
Series N	Maintenance: international sound programme and television transmission circuits
Series O	Specifications of measuring equipment
Series P	Telephone transmission quality, telephone installations, local line networks
Series Q	Switching and signalling, and associated measurements and tests
Series R	Telegraph transmission
Series S	Telegraph services terminal equipment
Series T	Terminals for telematic services
Series U	Telegraph switching
Series V	Data communication over the telephone network
Series X	Data networks, open system communications and security
Series Y	Global information infrastructure, Internet protocol aspects, next-generation networks, Internet of Things and smart cities
<b>Series Z</b>	<b>Languages and general software aspects for telecommunication systems</b>
